Section IV

Applications Satellites, the Environment, and National Security
In his classic political history of the early Space Age, Walter McDougall explained the cold war competition between the Soviet Union and the United States as a competition between two increasingly technocratic states. In the American case, his narrative represents a cry for restraint. The technocratic imperative is not a democratic one. He saw in the coming of technocracy the rise of a narrow, technologically focused elite to power. He apparently did not like the technocratic vision of the future this gave him; not surprising, I think, given his experiences in one of American technocracy’s great Apollo-era disasters, the Vietnam War.

But one of the key traits of technocracy is the state’s effort to use “technology,” often defined very amorphously, to improve lives. This is, I think, what Steve Dick meant when he asked me to discuss the societal impact of military, applications, and science satellites. The United States government has financed these in the general belief that they would result in progress of some sort. In many cases, the hoped-for outcomes were obvious. Everyone thought weather satellites would result in longer-range weather forecasts, an economic, as well as a social, good. Military satellites, too, had obvious uses. The earliest military satellites were oriented toward surveillance and intelligence gathering, developed to supplement intelligence aircraft.

The same can be said about the literature on applications satellites. To date, only communications satellites have a significant literature, as David Whalen will discuss in his paper. Only military satellites, my first topic, have received extensive study, although to date imaging satellites have drawn most attention, leaving several areas untouched. It is also the case that many “big picture” questions about the impact of these vehicles on the military, and on our political culture, have yet to be asked.

Even scientific satellites were often utilitarian in nature. Asif Siddiqi wrote in his essay for the 2005 Critical Issues conference that “[T]he literature on the history

Societal Impact of Spaceflight

of space-based science has, however, not been significant.” 2 Indeed it has not! Very few efforts in space science have drawn scholarly attention. But scientific satellites and solar system probes have had profound impacts on the scientific community and, as is the case with military satellites, on our national politics.

Satellites and the Military

One of the fundamental historical realities exposed in all of the papers in this session is that satellites have been seen, since Sputnik, as militarily useful. The first weather satellite, TIROS, started its road to existence as an Army reconnaissance satellite project at Fort Monmouth, New Jersey, a couple of years prior to Sputnik’s launch. Army leaders thought, quite rightly, that just as airborne reconnaissance had transformed knowledge of the battlefield in World War II, spaceborne reconnaissance would cement that tactical advantage and make it a global, and strategic, asset. It would also place that asset under Army control, relieving the institution’s dependence on its chief rival, the U.S. Air Force, for intelligence. They were thwarted by President Eisenhower, who gave imaging reconnaissance to the Central Intelligence Agency and the Air Force, weather satellites to NASA and the Weather Bureau in an unsuccessful partnership arrangement, and to his own former service, the Army, communications.

There is already some good literature on reconnaissance satellites and their impact on the cold war. Jeffrey Richelson has examined two important systems in a pair of books, the Defense Support Satellite Series, which served to provide early warning of Soviet ballistic missile launches, and the Keyhole series of imagery satellites (also known as Corona and Discoverer.) The Corona satellites have also drawn attention from Dwayne Day, from a policy and technology perspective. There is also at least one popular treatment of space surveillance.3

A thorough overview of what’s often called “MILSPACE” can be found in Stephen Johnson’s article in the *Critical Issues in the History of Spaceflight* volume, so instead of repeating his work I want to highlight a few areas that seem particularly interesting.4

From a technological standpoint, several types of intelligence satellites have existed since the late 1960s that haven’t been examined. Since the early 1980s, the United States has flown a series of synthetic aperture radar satellites known as Lacrosse (and sometimes Onyx). These satellites are intended to detect vehicles of all types and can also detect motion and change. The first civilian synthetic aperture radar (SAR) flew in 1977 and, as far as I can determine, the first intelligence SAR was initiated in 1976. The Jet Propulsion Laboratory (JPL) built the first civilian SAR but does not seem to have been the source for the military version.5 Are these truly independent developments? Or is there a relationship between the two? Our current understanding of space history would pretty strongly suggest that there must have been a relationship between the two. John Cloud has described the relationship between classified imaging satellites built for intelligence purposes and their unclassified counterparts (i.e., Landsat) as a shuttered lamp—a relationship controlled by the intelligence community.6 The radar case might show us that the relationship between civilian and military technology is more complex than this model.

There are also other kinds of intelligence satellites. As was revealed at least as far back as the early 1980s, the United States operates “signals intelligence” (SIGINT) satellites. These satellites capture millions of electronic signals every day that are analyzed by an ever-changing array of supercomputers. There are many possible stories to tell buried in this topic. As Stephen Johnson also pointed out, the technologies underlying SIGINT are in need of historical exegesis.7 The political, military, and intelligence utility of these kinds of systems is in need of study, too. In the early 1990s, the U.S. National Security Agency apparently considered using it for industrial espionage against our European allies. This briefly produced diplomatic problems for the United States (whose governmental allies were, apparently, quite content with the system’s existence until their publics found out about it).8

---

The history of this technical capability is also directly relevant to the current administration’s attempts to discredit revelations that it is using signals intelligence to spy on terrorists (and everyone else, too). The historical fact of the matter is that this is old news. The technical capacity to do this has been a matter of public record since the public unmasking of the National Security Agency in the Ford administration and its role in illegal domestic surveillance; wise leaders should assume enemies have a basic awareness of our capabilities—particularly old, well established ones. The subject of signals intelligence and its use and abuse deserves further historical exegesis.

Better covered historically than signals intelligence has been the development of military communications satellites. So far, the literature suggests that although the military saw the utility of surveillance satellites well before the ability to build them existed, the armed services rather missed the boat with communications satellites. The first communications satellites that we’re aware of were commercial. AT&T immediately sought a monopoly in this new business and was denied by government policy; the Department of Defense (DOD) seems to have bought access to the technology in the early years. It became an innovator later in the Space Age. One author places responsibility for this in the decision to place communications satellite development in the Army and in the Advanced Research Projects Agency, delaying development until after private companies had already flown their satellites. NASA also played a significant role in communications satellite development in the 1960s and early 1970s, although apparently not after that. To make this picture of innovation still more complicated, I was recently told by a retired NASA manager that the Air Force paid for a significant fraction of the last of NASA’s Advanced Technology Satellite comsat series, ATS-6, launched in 1974.

10. The technical capability to carry out large-scale eavesdropping on electronic communication was revealed in the 1970s, when the National Security Agency’s illegal activities in spying on Americans was investigated by Congress. See James Bamford, The Puzzle Palace: A Report on America’s Most Secret Agency (Boston: Houghton Mifflin, 1982), esp. pp. 280–308. The role of satellites in this system is not clear; much of what was revealed during the 1970s involved wiretapping and interception of radio communications from ground-based “listening stations.” As Dwayne Day has shown recently, signals intelligence satellites first flew in 1960, although these seem to have been radar intercept satellites for characterizing air defenses, not communications intercept satellites. See Dwayne A. Day, “Early American Ferret and Radar Satellites,” Spaceflight (July 2001): pp. 288–293.

Communications satellites have had a profound impact on the armed services. My own former service, the U.S. Navy, evolved command traditions over 200 years that were based on the unreliability and often non-existence of communications with the National Command Authority back in Washington. Even radio did not fundamentally change this reality, because the high-frequency radios that were the basis of World War II communications were “environmentally unreliable.” As radio engineers all knew, sometimes one could get global range from a radio set—and sometimes you couldn’t reach a ship 50 miles away. The Navy continued to operate under the expectation that senior commanders were unlikely to be immediately available.

Satellite communications changed that. Essentially instantaneous communications were possible from virtually any spot on Earth or in the air above it after the mid-1960s. In addition to the culture shock this imposed on the Navy (and which it is still dealing with), I rather suspect it accounts for some of the severe cultural differences between the relatively new Air Force—which has only existed in the era of electronic communications—and the Navy. But in any case, buried in the history of military communications satellites are stories of cultural change as well as technological change, deserving of documentation and analysis. There are also, of course, changes in operations and in operational capacity due to this capability in need of examination.

Although there is at least some literature on communications satellites, largely missing from the historical record is an examination of the first military navigation satellite series, Transit. Operational in 1962, Transit was a Navy project implemented by the Applied Physics Laboratory of the Johns Hopkins University. Transit operated until 1996. The technical literature contains articles on its genesis, but I can identify no examination of its impact on Navy operations, capabilities, etc. Yet Transit was simple and inexpensive, and it was part of the justification for belief in “faster, better, cheaper” in the 1990s within NASA. It also paved the way for the NAVSTAR Global Positioning System, which one paper in this book addresses. So it had important ramifications but it hasn’t found its historian yet.

The last kind of military space technology that I want to discuss is weather satellites. The United States has maintained a civilian weather satellite series since 1960 and a military weather satellite series since 1961. President Eisenhower had intended that there be a single system operated by the Weather Bureau, but the resulting agreement collapsed very quickly. The prime justification for splitting into two satellite systems was that the DOD and the Weather Bureau wanted different overpass times, with DOD officials wanting an early morning orbit that would

---

permit planning of reconnaissance and aerial refueling missions. One source also states that the civilian system would not overfly Moscow, increasing the Pentagon’s desire for a different orbit choice. I rather suspect that the Pentagon’s desire for control also had a lot to do with this decision.

Initially, the two organizations used two variants of the TIROS satellite, with very similar instrumentation. This changed over time and, although the current civilian and military satellites use the same “bus,” they have different instrumentation. It is the military weather satellites that have provided strong evidence that the Arctic ice cap is shrinking rapidly, for example—a capacity the civilian satellites do not have. Other than R. Cargill Hall’s recent short, and very technically oriented, history of the Defense Meteorological Satellite Program, however, there are no studies of DOD’s weather satellite system or its evolution. My own forthcoming work deals only with the civilian system.

A Larger View of Military Impacts

Paul Edwards expounded a thesis a few years ago that in constructing its network of surveillance and communications assets, the DOD sought nothing less than a “closed world”—an Earth in which nothing could happen without the Pentagon’s knowledge. His argument is more sociocultural than historical, and I am not convinced. The sheer arrogance of such a goal (not to mention its technological unlikelihood!) gives me pause. Yet he might be right. The very name of the DOD’s communications architecture, The World Wide Military Command and Control System, certainly suggests that he is right. Rigorous investigation of his claim would tell us a great deal about the DOD and its leaders’ faith in technology if someone were willing to dig into it.

All in all, the extant historical literature on military use of space pretty strongly suggests that surveillance and communications have been stabilizing influences in terms of the strategic deterrence and the cold war contest with the Soviet Union. That’s the point made by Glenn Hastedt in his paper in this book. It’s far less clear that this is true in terms of the myriad “small wars,” “regional conflicts,” and “operations short of war” that the United States has engaged in since 1945. It’s likely true that these space assets have expanded the United States’ ability to engage in so-called conventional war, the sort fought by large formations of men and machinery.

---

14. Dwayne Day comments on an earlier draft of this paper, September 2006.
One recent analysis describes the very conventional first Gulf War as the first “space war.” Yet satellites have not similarly improved the nation’s capability to wage “guerilla war”—we remain poor at it, as the current wars in Iraq and Afghanistan show, and as was also true in Vietnam. The impact of space technology has been profound, in other words, but not limitless.

Further, one should wonder whether the global view offered by our space assets have encouraged the belief prevalent among neoconservatives that we can construct and maintain a perpetual Pax Americana. Based on a presumed “Revolution in Military Affairs” that derives from the integration of space-based communications, intelligence, and space- and airborne weapons, they contend that America can maintain and expand its dominion over Earth forever. In their 1998 program for America, for example, the movement’s leaders called for the development of “global missile defenses to defend the American homeland and American allies, and to provide a secure basis for U. S. power projection around the world,” and for establishment of control over “the new ‘international commons’ of space and cyberspace.” Their faith in technology and the utility of the space weaponry seems to me founded directly on a heavily distorted view of space capabilities.

In fact, they seem to believe in exactly what Edwards claims the Pentagon did in the 1960s—that a closed world is possible and desirable. There is a great subject here for someone to dig into. Satellites may very well have encouraged the rapid rise of militarism in the United States as well as encouraging our political classes to undertake global wars of choice.

**CIVILIAN APPLICATIONS SATELLITES**

So, I claim, military satellites of many descriptions and functions have had significant impacts on the American military, and may have had far larger impacts on American political culture. What about their civilian twins?

NASA launched the first civilian weather satellite in April 1960. This was TIROS 1, the direct descendant of the U.S. Army’s work toward an imaging

---

surveillance satellite. It was hugely popular, drawing a large, front-page *New York Times* article, complete with “cloud pictures” from space. NASA officials used it to sell the agency to Congress and the public. Better weather forecasting was the first obvious and direct benefit to non-astronaut, ground-dwelling humans (i.e., 100 percent of the American population).

Yet there is no published history of the weather satellite program. The last attempt at a history was Chapman’s study of the conflict between NASA and the Weather Bureau over control of the technology completed back in 1967.\(^{21}\) It was rather heavily redacted due to DOD concerns. Since then, no one has found the subject worthy of historical study. Not even the Weather Bureau’s descendant, NOAA, has bothered. The agency doesn’t even publish data on economic benefits from weather satellites. There is a single essay touching on weather satellites in the *Exploring the Unknown* series.\(^{22}\) What gives here?

My speculation on the subject goes like this: Weather satellites did not live up to the grand promises upon which they were sold. Using them, meteorologists of the 1960s thought they could produce monthly forecasts of great accuracy. As I show in my forthcoming work, however, by the late 1960s simulation studies done at the Goddard Institute for Space Studies showed that forecasts of more than a dozen days were completely impossible and forecasts of more than five days were impossible with current technologies. This was confirmed by the Global Atmospheric Research Program in 1978, a hugely demoralizing outcome to NOAA and to the meteorological profession. Satellite data emerged from this in such low regard that NOAA didn’t use it in routine operational numerical forecasting until 1998.\(^{23}\) So I rather suspect NOAA leaders have not wanted to undermine themselves with a historical study.

I do not want to leave the impression, however, that the weather satellites have been without impact. The geosynchronous satellites provide the hurricane and typhoon warnings and imagery and track forecasts that we’ve been accustomed to since the early 1980s. I suspect that they’ve also improved severe storm forecasting in the Midwest. Meteorologist friends of mine say this is true, anyway. Both of these are significant economic and human goods, although the lack of research on these topics available makes it impossible to make the case with any rigor. These satellites have also transformed the meteorological profession. Although operational forecasts in the United States have not used the satellite data, researchers and research-oriented forecast models have been using it routinely since the early 1980s.

It has led to much greater understanding of the structure of the atmosphere and its organization, particularly over the otherwise data-sparse oceans. Satellites permitted identification of the region of the Atlantic where hurricanes typically form, for example, something that hadn’t been known prior to the Space Age.

There is also a policy issue to be discussed. The United States has not flown a new instrument on its civilian, polar-orbiting weather satellites since 1978. This is not a failure of innovation; NASA is flying relevant research instruments and NOAA has developed airplane-based demonstration instruments as well. But NOAA hasn’t been able to get any of these instruments into space. This problem has been exacerbated by the 1994 decision to merge the civilian and military weather satellite programs into the National Polar Orbiting Environmental Satellite System, whose 1998 launch date has been “slipped” to somewhere around 2013–2014.24 There’s a gross policy failure here, and possibly several policy failures all working together to produce an exceptionally bad outcome.

Finally, in his recent movie, An Inconvenient Truth, former Vice President Al Gore, Jr., shows an image of Earth from space, taken by Apollo 17 astronauts from lunar orbit in 1973.25 By showing the “Big Blue Marble” in all its beauty and fragility and free of arbitrary, human-drawn political borders, it provided a potent symbol for environmentalists to rally around.

Although I certainly agree that images have great power, I have always wondered a bit about the specifics of this story. The first Earthrise image was sent back by a robot, Lunar Orbiter 1, in 1966. The first full-disk color image of Earth was actually sent back by Vern Suomi’s experimental spin-scan camera on the communications satellite ATS-3 in 1967. Yet only meteorologists talk about this image. In 1968, Apollo 8 astronauts took the first color Earthrise image. All of these images appeared in public media before the first Earth Day in 1970; the Apollo 17 images did not. The space program as a whole produced a series of stunning images that placed Earth in a context far different than Americans’ daily experience. I think the steady stream of dramatic imagery mattered more to the spread of environmental consciousness than any single picture.

I have touched on some of these issues in my own forthcoming history of atmospheric science, but since my focus is on NASA science, a lot of the above ground is essentially untilled. In terms of “societal impact,” I suspect that the weather satellites have been enormously important—but neither I nor any other scholar has made the case with any rigor.

Commercial communications satellites do not have quite the historical lacuna that the weather satellites do. Because David Whalen addresses them in his paper, I am not going to say much about this subject other than to reiterate what I said in the above Military Impacts section: although we have some good treatments of the evolution of comsat technology and of the policy issues surrounding them, no one has made the leap yet to societal impact. The economic value of the industry seems clear from Whalen’s work but there’s more to society than the pure social construct we call “money.” We often believe that our technologies make our lives “better” in some meaningful way, although one should always consult Ruth Schwartz Cowen’s book *More Work for Mother* before making this claim too strongly! Have communications satellites done so? I am reminded of Bruce Springsteen’s lyric “57 channels and nothing on.” Satellites have brought me hundreds of channels; I watch two regularly.

But let me dig a bit further into this question of “impact.” In one of his exploration essays, Steve Dick threw out the idea that communications satellites have brought the world “closer together.” The airplane was similarly touted as having the potential to “bring the world closer together” and other happy things—bring peace on Earth through greater understanding among peoples, etc. Joe Corn wrote a wonderful book on this. But the airplane’s legacy is far more mixed. It is true that I can take a relatively short flight to Tokyo to visit the land of sushi. It’s also true that the airplane allowed us to nearly wipe Tokyo off the map two generations ago, without even bothering with nuclear weapons. The airplane’s legacy is so mixed and contested that the nation’s shrine to aviation, the National Air and Space Museum, is not allowed to construct interpretive exhibits about it. Interpreting the airplane accurately would offend powerful political and economic interests.

My personal sense is that the same will turn out to be true for communications satellites: the legacy will be heavily mixed. It is certainly true that satellites facilitate emergency communications and they provide the opportunity for vastly more programming. At the same time, we have seen the growth of targeted media—channels that exist to promote specific interests or specific politics. The same capability that enables dedicated sports networks (e.g., ESPN, NESN) also permits Al Jazeera, the first independent Arab media organization (despised by the American

political right), and News Corp’s Fox News channel, derided by American liberals as “Faux News” for its blatant political bias.29

George Orwell feared that the end of the twentieth century would bring a perfect surveillance state into existence. Big Brother would be watching all of us, all of the time. We are not quite there yet, but we have achieved a world full of specialized propaganda bubbles—hidden behind the euphemisms of “targeted media” or “narrowcasting.” One can go through one’s daily life and never be subjected to uncomfortable or challenging ideas—or even facts. In short, we have a postmodern version of Orwell’s Ministry of Truth.

This is not the fault of the technology exclusively, of course. The Reagan administration’s elimination of the old Fairness Doctrine that required the airing of multiple viewpoints is another key enabler of this unfortunate outcome. It is also not new. Most major European cities have had partisan newspapers for centuries and the United States has its share of political magazines, the famous ones being *National Review* on the right and *The Nation* on the left, although there are others. But there are differences. Television is more immediate and immersive than print and has much greater emotional power. Whether these differences are sufficient to make a difference in how the newly partisan electronic media affects the nation is a subject worthy of study. To wrap up this brief discussion of communications satellites, I am not at all sure Dick’s optimistic appraisal is warranted.

Finally, the last applications satellite type I’ll discuss in this extended editorial essay is land use. As Pam Mack has shown in her book on Landsat, there were many possible and interested users of satellite-based land imaging during its developmental period, and their competing goals and interests made development of the system very difficult.30 And partly because of this, and also partly due to Pentagon restrictions on allowable spatial resolution (because of ill-conceived Congressional efforts to force “privatization” of Landsat), Landsat has never achieved a large enough user base to pay for itself. Instead, its imagery has been used by researchers, not by the economic interests that might be able to afford it on a commercial basis.31 Indeed, the primary

---

buyer of the data has been the intelligence community, which apparently finds that Landsat data serves as an effective supplement to its own classified imagery sources.

The satellite series itself has lurched from one crisis to the next, with each administration since Reagan willing to commit to only one more mission prior to commercialization; with commercialization never succeeding, each new administration has had to cope with the question of how to continue the series. The fundamental policy issues of what agency should maintain the capability and who should pay for it have not been resolved. So Landsat has been a technical success, but programmatically its history has been tortured. At the very least, there’s a good policy study here for someone interested in the subject.

**Earth Science From Space**

This is the subject of my own recently completed history of atmospheric science at NASA, so what follows is an essay on my own findings in the context of what very little else has been done on this subject. NASA’s scientific satellites, and—a very important point—its planetary probes, have revolutionized our understanding of Earth, its processes, and our place on it. They have also radically altered our beliefs about the solar system and the universe around us. Finally, they have fundamentally changed our national politics.

There is, to date, not a single history of any NASA Earth science program. The only work that even comes close is Henry Lambright’s monograph. Yet as several (non-NASA) studies show, the Agency’s stratospheric ozone research program initiated in the early 1970s led directly to the worldwide banning of a class of highly profitable chemicals. NASA research provided the first conclusive evidence that human activity was capable of causing global-scale damage. Yet these studies are not aimed at NASA’s science program. They discuss the politics and policies surrounding the 1987 Montreal Protocol. The political angle is important to these studies because ozone science was politically controversial, with leaders of the American political right claiming for many years that the idea of ozone depletion was an environmentalist hoax. Congressional hearings in 1995 underscored this view. But these earlier studies leave the reader wondering how NASA wound up leading this research field.

This is particularly germane as NASA’s role in the ozone wars led to repeated and long-running attacks on the agency on the editorial page of the *Wall Street Journal*, by Rush Limbaugh on his radio show and in his best-selling books, and by a

---

small constellation of other lesser actors in the right-wing political journals: *Reason*, *Commentary*, and *National Review*. The current administration made a brief attempt to quash NASA’s James Hansen, the agency’s most prominent climate modeler. But he was not the first NASA scientist to be attacked by what journalist Bill Moyers accurately terms the “radical right.” That honor actually belongs to Robert T. Watson, head of NASA’s ozone research program in the 1980s.

In *High Speed Dreams*, my history of supersonic transport research, I suggested in my conclusion that NASA’s entry into political controversy came with its decision to embrace stratospheric ozone as a research program in hopes of absolving the Space Shuttle of claims that its solid rocket boosters would damage the ozone layer. But in fact, the Agency’s conflict with the New Right political movement that came to power with Ronald Reagan has its origins much earlier, in the Agency’s planetary missions of the 1960s. The JPL’s Mariner Venus and Mars missions showed NASA’s scientists—those employed by the Agency as well as university-based scientists involved in them—that relatively small initial differences between the three “terrestrial” planets (Venus, Earth, and Mars) had led to huge differences among these planets as they exist today. This fact, obvious by 1965, forced NASA’s scientific constituency to start to come to grips with the relationship between chemistry and climate.

Probably the best known expression of this is in James Lovelock’s Gaia hypothesis. Lovelock, who consulted briefly at JPL in the early 1960s, argued that biological activity regulated Earth’s climate via its impact on atmospheric chemistry. But he was not the only person making chemical claims about climate by the end of the 1960s. Carl Sagan, never a NASA employee but always associated with the

---

Agency anyway, did a relatively speculative study for JPL on Venus’s climate in 1960 and did a series of comparative studies between Earth, Mars, and Venus over the course of his career. His first graduate student, James Pollack, built NASA’s planetary climate modeling program at the NASA Ames Research Center. 38

It was also Pollack’s group at Ames that produced the “nuclear winter” hypothesis in 1984, bringing down right-wing opprobrium on NASA while also stimulating tropospheric aerosol research. 39 The nuclear winter hypothesis helped trigger the foundation of the George C. Marshall Institute by Robert Jastrow. Jastrow, horrified by what he saw as a deliberate political attack on the Reagan administration disguised as science by Sagan, Pollack, and other scientists (including Donald Kennedy, the current editor of Science), appealed to conservative foundations for funds to finance a pro-nuclear “scientific” organization. He envisioned it as the conservative response to the Union of Concerned Scientists. 40

Planetary climate studies also landed on the East coast, NASA’s Goddard Institute for Space Studies (GISS). This organization, founded (somewhat ironically) by Jastrow in 1960, was intended to be the Agency’s center for theoretical study of planetary atmospheres. That’s still what it does. Unlike Goddard, Ames, and JPL (all of which also retain experimental and hardware programs), GISS is primarily theoretical. In modern space science, theory and data are both examined through the use of models. GISS actually performed the simulation studies that suggested weather satellites of the 1970s would not produce a great improvement in daily weather forecasts, for example.

GISS, of course, is also the home of NASA climate modeler James E. Hansen. Hired there in the early 1970s, Hansen initially worked on a scattering model for Venus’ planetary cloud layers. Jule Charney, founder of numerical weather forecasting, performed some regional (Earth) climate studies using a GISS weather model in the middle of the decade; these, and Pollack’s comparative planetary studies, triggered Hansen’s interest in Earth’s climate. Hansen and his colleague at GISS, Andrew Lacis,
came from the University of Iowa. Hansen considers his intellectual forebears to be the late James van Allen of Iowa and Jule Charney.\textsuperscript{41} He began building GISS's climate modeling capabilities in mid-decade.

Hansen's climate model was one of two that formed the basis of the first declarative study by the National Academy of Science on the subject of global warming, the 1979 “Charney Report.” In its preface, the University of Wisconsin’s Verner Suomi stated that there was “no reason to doubt that climate changes will result and no reason to believe that these changes will be negligible.”\textsuperscript{42} Every study by the National Academy of Science since has ratified its conclusions, as has the Intergovernmental Panel on Climate Change in each of its three assessments of climate science since its foundation in 1988.\textsuperscript{43}

Global warming is caused by human emissions of carbon dioxide, which exceed volcanic output by more than 150 times. Carbon dioxide is a chemical, of course, although one that is currently difficult to measure accurately from space. Sagan was the first to blame Venus’s extremely hot climate on a surplus of this gas; Venus, American and Soviet robotic spacecraft found in the 1960s and 1970s, has about 300 times as much atmospheric carbon dioxide as Earth. And these facts bring us back to my claims about chemistry, climate, and NASA’s role in fostering political controversy.

To be blunt about it: NASA has shown conclusively that humans cannot continue to change the chemistry of Earth’s atmosphere without enormous, and negative, consequences. One of these consequences is ozone depletion, a cancer risk. The larger consequence is global warming. A 1983 National Academy study laid out some of the problems for the United States: much of the irrigated area of the southwest would have to be abandoned unless sufficient additional water could be imported. The highest forecasts of sea level rise would leave most of coastal America underwater unless defended by dikes of 15 to 20 feet (5 to 6 meters)—quite an expensive undertaking along several thousand miles of coast.\textsuperscript{44} Further, this committee pointed out, “[I]ncreasing carbon dioxide is expected to produce changes in global mean temperature that, in both magnitude and rate of change, have few or no precedents in the Earth’s recent history.”\textsuperscript{45} This had led much of the

\textsuperscript{44} NRC, \textit{Carbon Dioxide and Climate}, 1983, p. 46.

\textsuperscript{45} NRC, \textit{Carbon Dioxide and Climate}, 1983, p. 51.
committee to a state of “unease,” as they put it, because they could not assume that the effects would appear in a gradual, linear fashion.

Yet these facts are a direct affront to the belief system that dominates the American political right. Beginning with the popular work of famed economist Milton Friedman, the American right has adopted a worldview that equates economic freedom with political freedom.46 Although this is historical fantasy—we have never been a free-market nation—this belief system forces its adherents to deny the reality of the scientific community’s fact claims. True believers seek to protect their faith by denying inconvenient facts, and they believe that no scientific agency of our government has done more to undermine what George Soros has called “free market fundamentalism” than NASA has.47 The accepted facts are that unregulated carbon dioxide emissions are the cause of global warming; solving the problem will require regulation of some kind. Such regulations would violate fundamental precepts of free-market theology, so the rightists have decided to reject the facts. Instead, they have formulated a convenient set of conspiracies. And, perhaps further reinforcing my point about “targeted media” above, a recent Pew Research Center for the People and the Press poll indicates that 43 percent of college-educated Republicans reject the fact of global warming, whereas only 25 percent of Democrats do.48

Hence, if one reads what’s published in the rightist political literature mentioned above, one will find environmentalism equated with communism throughout the 1980s and 1990s, and with terrorism after 2001. One will also see scientists, including NASA scientists, derided as dupes and frauds for promoting “environmentalist nonsense.” The “hidden agenda” of these scientists, in the words of one writer, is “against business, the free market, and the capitalistic system.”49 In the words of

---

49. S. Fred Singer, “Global Warming: Do We Know Enough to Act?,” p. 45. For a larger discussion of the political affiliations of the global warming denial effort see Lahsen, “Climate Rhetoric: Constructions of Climate Science in the Age of Environmentalism.”
another, global warming is merely “a means of achieving an egalitarian society.” It is this literature that Senator James Inhofe (R–Oklahoma) and his colleagues draw on when they denounce global warming as “the greatest fraud ever perpetrated on the American people.” A new book from the Competitive Enterprise Institute puts it still more bluntly, calling them anti-American, anti-capitalist, and anti-human; to make clear their linkage to communism, they are “green on the outside, red to the core.” “Commissies,” as it were, in green makeup. To be clear, these political actors are not merely attacking leftist politicians. They attack practicing scientists for the results of their research—the very content of science. One journalist has labeled this assault “The Republican War on Science.”

One can argue, as physicist William Nierenberg did in the National Academy of Science’s 1983 study of global warming, that the phenomenon is real and is likely to have severe consequences, but we don’t need to do anything about it. Human civilizations have come and gone as climate changed around them; survivors simply migrate and rebuild elsewhere. This is scientifically, and historically, entirely correct. One can argue about the ethics of such an approach—I would not subscribe to it—but it is correct and honest. One does not have to deny the legitimacy of a science to defend capitalists’ right to pollute; in a pluralist, democratic society, one can simply accept Nierenberg’s argument that we adapt to the new, warmer world.

Yet this not the argument being made by the global warming deniers. Instead, they have chosen to demonize working scientists by applying the McCarthyite tactic of linking them to communism and accusing them of a global conspiracy.

This extreme reaction against climate science by the American right is not merely a quibble over interpretations of data. And it is not happening simply because ExxonMobil has spent millions of dollars a year supporting the denial industry.
It is a defense of a political ideology. Nothing else adequately explains the rightists’ reaction to a half-century of scientific research.

I do not wish to make too much of NASA’s role in the science of global warming. As Spencer Weart’s recent history of global warming shows, there are many other threads to that story. But since the late 1970s, NASA funding for climate science has overwhelmed all other sources. It is by far the dominant funder of the current Climate Change Research Program, a fact in need of explication. Of the $1.86 billion dollars spent on climate science in fiscal year 2005, NASA spent $1.24 billion. The next largest funder, the National Science Foundation, spent $198 million that year. NASA’s interest in planetary climates stemming from the Mariner missions of the 1960s, and the seeming need for a global view of global warming, made its entry into this research field an obvious choice.

It’s also true that these controversial fields were not originally as politically charged as they are now. During the 1970s, both American political parties accepted the reality of environmental damage and argued over policy details: the most efficient form of regulation, standards of evidence, how to determine when a sufficiency of evidence existed to base regulation upon. The modern anti-environmental movement—often it is called “pro-business” to disguise its true nature—started in the Western states at the same time and achieved its first national expression with Reagan’s election. When NASA officials decided to enter these fields, the technocratic impulse still ruled: once one understood the science, science-based regulation would follow. It made sense to them to try to lead in fields relevant to the agency’s technological capacities. As technocratic managers, they also didn’t expect that anti-environmentalism would wind up dominant 20 years later. The magnitude of the controversy they entered came as a surprise.

Inside the scientific community, the intersection of space science and Earth science also engendered controversy. Lovelock’s Gaia hypothesis was widely criticized for its depiction of Earth as a self-regulating organism. In one paper he used a metaphor of a planetary engineer to describe how the integrated Earth system worked. This had obvious metaphysical implications that he later regretted. In short, he was attacked for Gaia’s religious implications. But his view of planetary climate as a system of

nested feedback-control systems involving what came in the 1980s to be called “biogeochemistry” was ultimately highly influential. In 1986, a group of scientists working under a NASA charter created a new, less offensive label for this integrated view of Earth, “Earth Systems Science.” One can find textbooks bearing this name in university bookstores now and some universities have integrated their separate geology/geophysics/atmospheric/ocean science programs into a single department. The California Institute of Technology’s integrated department is Earth and Planetary Sciences, while the University of California, Irvine called its program Earth System Science (it was organized and named by a former NASA scientist, Michael Prather). Earth sciences are in the midst of a sea change in organization and, I think, their intellectual structure, inspired by the availability of planetary-scale data.

Satellites seem to have disappeared from my narrative, so let me bring some back in. I have ignored solar physics and the tightly linked field of space weather. Our friendly local star’s radiation and particulate output affects Earth’s upper atmosphere, and solar radiation trapped by Earth’s magnetic field does as well. These also affect satellites in Earth orbit and deep space probes. Because satellites have significant economic and military value, NASA, the DOD, and NOAA have all spent quite a bit of money over the last several decades on satellites and model studies aimed at understanding and predicting these effects. Scientists are also interested for the intrinsic scientific questions involved, of course—the motivation isn’t solely utilitarian!

Three recent works discuss the evolution of solar science and space weather—the border between these two issues being, like space itself, rather tenuous. Karl Hufbauer’s book *Exploring the Sun* focuses exclusively on the history of solar physics and the solar wind. He does not discuss their influence on Earth. Two other works make attempts at this. In *Storms from the Sun*, Michael Carlowicz and Ramon Lopez focus on the impact of solar eruptions on telecommunications and electrical power distribution networks. But their work is weak on the science and on the historical evolution of the field.58

A more useful treatment of the subject is Barbara Poppe’s and Kristen P. Jorden’s *Sentinels of the Sun*. Written largely from NOAA’s perspective, this work focuses on the evolution of space weather forecasting with that agency. It gives the reader a good sense of the bureaucratic politics of the issue. Unfortunately, it is completely undocumented and, while it leaves the reader with the understanding that NASA and the Air Force have always been parallel actors in the field of space weather, it tells us little about their respective roles.59 There is plenty of room left for new research in this area.

The second type of satellite to discuss is oceanographic. NASA has flown satellite sensors aimed at both physical and biological oceanography. Neither type has been addressed in an historical study. The most significant of these has probably been TOPEX/Poseidon, a joint US-France mission that performed sea surface altimetry. Altimetry directly measures the height of the ocean surface; indirectly, it can tell us a great many other things about the oceans. Its most public outcomes have probably been in El Niño forecasting and in measuring sea level rise.

Scientifically, however, it may turn out to be revolutionary for its impact on ocean modeling. JPL and several other institutions are involved in a joint modeling effort aimed at transforming data from TOPEX/Poseidon and NOAA's Argo buoy network into a new, four-dimensional view of the world ocean. They are not done yet but, from what this group has published so far, they're building a radically new interpretation of how the ocean absorbs and distributes heat. In turn, this will affect scientific understanding of how the geographic distribution of heat and precipitation will change under global warming.

The final type of satellite I will discuss is geodetic. These measure the shape of Earth and its gravity field. They were among the first kinds of scientific satellites flown, as they are very simple by their nature and militarily useful. Earth's gravity field is not perfectly spherical—it has “bumps” due to local concentrations of higher-density material within Earth—and the DOD wished to know where these were for more accurate targeting of nuclear missiles. Dwayne Day has published a set of articles on military geodetic satellites, the first historical studies on this subject.

At NASA, the Goddard Space Flight Center has led the development of this technology until very recently. In collaboration with the DOD, NASA has flown a series of these satellites. These haven’t been part of the Agency’s “controversy portfolio,” however, perhaps because most of the public has no idea what they do. But that’s likely to change because the latest geodetic satellite, the JPL's GRACE mission, is accurate enough to produce mass estimates for ice sheets and aquifers. Recently, the mission scientists have pronounced that their data shows mass loss from both Greenland and Antarctic ice sheets, thus sticking themselves directly into

the climate wars.62 There is a lot more historical work on the subject of geodetic satellites and their impacts on science, however. To date, very little examination or interpretation of this field has been done.

Space science, then—not merely Earth science but aspects of planetary science as well—has radically altered our beliefs about Earth and its processes. It has forced scientists, often against their own political preferences, to come to grips with the very uncomfortable notion that humans have become geological agents. We humans have the ability to change the basic conditions of life on Earth. The dominant belief from the nineteenth century—that humans were too puny to have any significant impact on Earth—can no longer be sustained in the face of NASA’s research. This is the root of the political problems faced by Earth scientists in the 2000s.

**Conclusion**

Much of the historical literature on the Space Age to date has focused on human spaceflight. To borrow the analytical terminology of feminist history of science, this privileges the narrative of a handful of transient males—the professional space tourists we call astronauts—over that of most of the species. But the largest impacts of space technologies to nonastronaut humans have come from robotic spaceflight. These impacts have been positive and negative, economic, political, scientific, military, and ideological.

Unlike humans (to date, at any rate), robot spacecraft can be engineered to live in space, providing routine data for sometimes decades. They can also be sent to places inhospitable or deadly to humans. This has been the source of their success as scientific explorers, routine storm monitors, communications facilitators, and intelligence gatherers. It is also probably why they have virtually no place in the narrative of space history to date. As nonhumans, they’re ignored. It’s far easier to write a compelling heroic narrative about human actors than robotic ones, and space history has often been little more than advocacy written in heroic prose.63

But engineering is a human endeavor as well. As the above discussion should suggest, spacecraft engineering is wrapped up in the politics of science and government—both human enterprises. The New Space History, as Roger Launius has called it, has plenty of room in it for this narrative as well. Precisely because there is so little already written, it’s also a rich area for research.

64. Launius, “Historical Dimension of Space Exploration.”
First, I believe that this nation should commit itself to achieving the goal, before this decade is out, of landing a man on the moon and returning him safely to the earth . . . .

Secondly, an additional 23 million dollars, together with 7 million dollars already available, will accelerate development of the Rover nuclear rocket . . . .

Third, an additional 50 million dollars will make the most of our present leadership, by accelerating the use of space satellites for worldwide communications.

Fourth, an additional 75 million dollars—of which 53 million dollars is for the Weather Bureau—will help give us at the earliest possible time a satellite system for world-wide weather observation.

John F. Kennedy
Special Message to the Congress on Urgent National Needs
25 May 1961

The Apollo 11 plaque states that the U.S. astronauts “came in peace for all mankind.” But long before the Apollo landing President Kennedy wanted the United States to be seen as running a high-technology program whose practical benefits would be for all mankind. Kennedy’s principal audience was meant to be the third world—as well as the U.S. public—but his message also provided “cover” for the Congressmen who would have to authorize billions of dollars for the Apollo program. The U.S. program would also provide practical, nonmilitary applications that would benefit all Americans as well as all mankind.

The military had already begun their program of applications satellites. By the time of Kennedy’s speech, the Department of Defense (DOD) had launched a whole generation of reconnaissance, navigation, and weather satellites. These systems
were operational and new generations were in the works. Strangely, this DOD litany of successful applications did not include communications satellites.

Much of the military thinking about space originated with RAND, a Douglas Aircraft Company Research and Development (R&D) unit at the time. On 2 May 1946, RAND published their famous “Preliminary Design of an Experimental World-Circling Spaceship.” Chapter 2 of this document, drafted by Louis Ridenour, was titled “The Significance of a Satellite Vehicle.” Greatest significance is given to the use of rockets (satellite vehicles) as bombardment vehicles, but next in importance was the observation capability of a satellite over enemy territory. This observational capability would allow weather observation before the raids and accurate bomb damage assessment after raids. The document also discusses the advantages of satellites as communications relay stations. The simplicity of operations if satellites are in geostationary orbits is addressed in passing. The value of then-current communications through the ionosphere is given as $10 billion.

In 1947 RAND published the first of many follow-ups to the 1946 report. These reports, prepared under the direction of James E. Lipp, covered a variety of topics. One report, “Communication and Observation Problems of a Satellite,” continued the discussion of satellite communications and brought up the issue of a “spy satellite” for the first time. RAND continued its studies of reconnaissance and weather satellites, in 1951 publishing a report titled “Inquiry into the Feasibility of Weather Reconnaissance from a Satellite Vehicle” by William Kellogg and Stanley Greenfield, and another report on the “Utility of a Satellite Vehicle for Reconnaissance” by James E. Lipp, Stanley M. Greenfield, and R. S. Wehner. Perhaps more important for the space race was an earlier RAND report entitled “The Satellite Rocket Vehicle: Political and Psychological Problems.” This document was considered by space historian Walter McDougall as “the birth certificate of American space policy.”

Communications satellites had their origins in science fiction and their first serious exposition by an AT&T engineering manager. Arthur C. Clarke (1917– ), then a Royal Air Force radar officer, published an article in the October 1945 issue

of *Wireless World* entitled “Extra-terrestrial Relays.” In this article he discussed the advantages of 24-hour geostationary orbits that would allow a satellite to maintain position over the same portion of the equator indefinitely. Clarke foresaw use of space stations at this altitude for radio and television broadcasting. John R. Pierce (1910–2002) was, like Clarke, a science fiction writer, but he was also an engineering manager at Bell Telephone Laboratories. In an article “Don’t Write, Telegraph,” published in *Astounding Science Fiction* in 1952, Pierce discussed some possibilities regarding communications satellites. In 1954 he was asked to give a space talk to the Princeton section of the IRE (the Institute of Radio Engineers, now the IEEE). According to Pierce, “The idea of communication satellites came to me. I didn’t think of this as my idea, it was just in the air. Somehow, I had missed Arthur Clarke’s paper on the use of manned synchronous satellites for communication.” In 1958 Pierce and his colleague Rudolf Kompfner prepared a presentation on satellite communications for a conference. This was later published in the *Proceedings of the IRE* in March 1959.

Thus, all four applications areas—reconnaissance, navigation, weather, and communications—had been discussed at some length in the immediate post-World War II period. Interest had accelerated in response to the U.S. Air Force spy satellite Request for Proposal in 1954, but the real push for applications satellites came as a response to Sputnik.

**Reconnaissance Satellites**

All of the early RAND recommendations had been for a “direct readout” satellite—one that transmitted pictures to the ground electronically. Many of the studies assumed a standard television camera. The Air Force (aided by its RAND think tank) had begun development of a reconnaissance satellite, Weapon System 117L (WS-117L), on 16 March 1955. The program, initially called Advanced Reconnaissance Satellite (ARS), then SENTRY, and finally Satellite and Missile Observation System (SAMOS), was slow to mature. By 1957, members of the Presidential Science Advisory Committee (PSAC) were dissatisfied with the Air Force program; they wanted a “film return” satellite and they wanted the program managed by the Central Intelligence Agency (CIA). The success of the U-2 seemed to indicate that the CIA was better at bringing new technology into operation in a short period of time. On 7 February 1958, President Eisenhower authorized the CIA to proceed with CORONA.

---

CORONA/GAMBIT

Within a few months, the WS-117L program had been reoriented to include CORONA (film return), MIDAS (early warning), and SAMOS (direct readout—later to include film return). The first Discoverer (CORONA) launch was on 28 February 1959; it was a failure, as were most launches over the next two years. The first successes were in August 1960 when reentry vehicles (SRVs) were recovered from the ocean and in mid-air. From 1959 to 1972, almost 150 CORONA (KH-1 through KH-4B GAMBIT) satellites were launched on Thor-Agena vehicles. After August 1960, most were successful.\(^\text{10}\)

From 1959 to 1971, CORONA was the principal U.S. reconnaissance satellite (along with a few ARGON and LANYARD special-purpose satellites). SAMOS was eventually cancelled. In 1960 a joint program office was formed and designated the National Reconnaissance Office (NRO). NRO was staffed by the CIA and Air Force. The existence of NRO was “revealed” on 18 September 1992. The entire CORONA program was declassified on 24 February 1995. Later programs are still classified, making accurate descriptions difficult.

The KH-7 and KH-8 GAMBIT satellites provided increased resolution (~0.5 m) over the CORONA satellites (~3 m). The CORONA satellites had grown in size from 800 kg to about 2,000 kg (two SRVs), but were all launched by Thor-Agena launch vehicles. The KH–7 satellites were launched on Atlas-Agenas. The heavier (3,000 kg) KH-8 satellites were launched on Titans. About 100 GAMBITS were launched between 1963 and 1984 with about a 95 percent success rate. Early GAMBITs had lifetimes of days but, over time, lifetimes grew to weeks.

The Rest of the “Spysats”

The Air Force had always wanted to put men in space; the Manned Orbiting Laboratory (MOL) was their great opportunity to do so. Although MOL had many goals, its primary purpose was the KH-10 (DORIAN) reconnaissance system. The vehicle would have weighed about 15,000 kg. First authorized in 1962–1963, MOL would eventually be cancelled in 1969 after an expenditure of billions of dollars.

Starting in the late 1960s, the United States and the USSR began discussing arms limitation. The Soviet Union had established—or was establishing—rough parity in nuclear weapons and intercontinental ballistic missiles (ICBMs). Both sides were developing anti-ballistic missile (ABM) systems. In the process of negotiating the Strategic Arms Limitation Treaty I (SALT I, the ABM Treaty), it was agreed

that “national technical means” would be used to verify compliance and that no interference with these means would be allowed. Spy satellites were legal!

It has been argued that the KH-9 was developed as a backup to MOL. The vehicle weighed more than 11,000 kg—almost four times the weight of a KH-8 GAMBIT and not much less than the MOL. Known as “Big Bird,” the KH-9 HEXAGON carried a television camera as well as film cameras and four SRVs. It was launched by Titan 3D rockets. Big Birds increased satellite lifetimes to months. Of 20 KH-9 launches, only one failed, the last launch in 1986. Declassification was progressing until the fall of 1997. There were even plans to place a KH-9 in the new Smithsonian hangar at Dulles Airport. According to Dwayne Day, a military space historian who has written about CORONA and other spy satellites, Big Bird probably “gathers dust in a classified warehouse . . . only a few yards down from the Lost Ark of the Covenant.”

Perhaps the biggest improvement in spy satellites was the all-electronic, direct-readout KH-11 Kennan/Crystal and its successor, the KH-12/KH-11B Improved Crystal. These satellites finally provide the capability that SENTRY/SAMOS hoped for: real-time direct readout—facilitated by communications relay satellites including SDS, TDRSS, and MILSTAR. About two dozen of these satellites have been launched. The Improved Crystal weighs almost 20,000 kg and can only be launched by the Space Shuttle or Titan 4. Lifetimes are now measured in years. The KH-12 carries about 7,000 kg of fuel and its lifetime is more than 10 years. In addition to the visible and infrared capabilities of the KH satellites, at least a half-dozen Lacrosse radar satellites have been launched.

Image intelligence (imint) and human (spy) intelligence (humint) have been supported by various forms of signal intelligence (sigint)—including satellite sigint. These include Navy systems from the 1960s (GRAB, DYNO, POPPY), ferrets launched with KH-9 satellites, Air Force systems (CANYON, VORTEX, MERCURY), and the CIA’s AQUACADE. Many of these satellites are now in geosynchronous or Molniya orbits—and are all but invisible.

Societal Impact of Reconnaissance Satellites

Both the United States and the Soviet Union had been brought into World War II as the result of surprise attacks. Each of these two countries suspected its rival of planning a surprise attack. Perhaps the greatest impact of reconnaissance satellites was reducing that threat. In the words of President Lyndon B. Johnson,

I wouldn’t want to be quoted on this, but we’ve spent thirty-five or forty billion dollars on the space program. And if nothing else had come out of it except the knowledge we’ve obtained from space photography, it would be worth ten times what the program has

cost. Because tonight we know how many missiles the enemy has and, it turned out, our guesses were way off. We were doing things we didn’t need to do. We were building things we didn’t need to build. We were harboring fears we didn’t need to harbor.  

**Navigation Satellites**

In the days immediately following the launch of Sputnik in October 1957, scientists and engineers worked to analyze the spacecraft’s signal and its orbit. Bill Guier and George Weiffenbach of the Johns Hopkins University Applied Physics Laboratory (APL) listened to the satellite’s signal and monitored the change in its frequency due to the Doppler effect. They used this Doppler shift to compute an orbit for the Russian satellite.

Another APL engineer, Frank McLure (1916–1973), realized that if the orbit were known, the Doppler information could be used to determine the position of the radio receiver on the ground. In early 1958, McLure described the potential for developing a space-based navigation system. Within a few weeks, APL proposed a navigation system to the Navy.

**Transit Satellites**

The earliest Transits were launched on the Thor–Able and Thor Able–Star rockets from Cape Canaveral. The very first of these occurred on 17 September 1959. The last two experimental Transit satellites demonstrated that precise navigation was possible using two frequency beacons broadcasting the satellite ephemerides (orbits). This system was so robust that it was capable of determining the harmonics of Earth’s gravitational field and the effects of propagation through the ionosphere. The last satellites were also able to demonstrate the availability of the satellites when in a near-circular orbit at about 1,000 km and inclined about 66 degrees.

After the poor reliability of the Naval Avionics Facility Indianapolis (NAFI)–built Transit satellites, RCA built the rest. It was always clear that Transit had significant limitations. The accuracy was good enough for nuclear weapons (<1 km) but not good enough for conventional weapons. The Transit position fixes took some time to obtain, making Transit almost useless for moving objects. The Navy continued research—especially at Naval Research Laboratory (NRL)—on improvements. In 1964, the Air Force started a new navigation satellite program, Project 621B.

**NAVSTAR/GPS**

By 1972, DOD wanted just one program: a system that could be used to navigate fast-moving aircraft and even to deliver conventional weapons. In 1973, the NAVSTAR Global Positioning System (GPS) program was approved. Over the next few years, arguments and tradeoffs between the Navy and Air Force were

---

adjudicated—mostly on their merits—and GPS Block I launches began in 1978. Transit was kept in operation until 1996.\textsuperscript{13}

GPS satellites are in 12-hour circular orbits inclined 55° to the equator—much higher than Transit. There are six orbital planes, each containing four satellites. Two L-band frequencies are broadcast (L1: 1575.42 MHz and L2: 1227.60 MHz) containing the time (Universal Time Coordinated and a Pseudo Random Noise code) and satellite position. Differences between the satellite time and the vehicle time provide range measurements—three range measurements allow a position to be determined within 10 to 100 m. The civilian Standard Positioning Service (SPS) signal has a conditional access code (CA) that degrades accuracy. This selective access means that civilian signal is not good enough to use for weapons delivery. Military users can get position to within a few meters.

A contract for eight Block I GPS satellites was awarded to North American (Rockwell) in 1974. A contract modification for four additional Block I satellites was awarded in 1981. NAVSTAR 12 was produced as the Block II qualification model. There was only 1 failure out of 11 launches. Block II/IIA added nuclear detonation detectors and many improvements. The satellite was still manufactured by Rockwell, but the launch vehicle was now a Delta 6925 for Block II and a Delta 7925 for Block IIA. There was only 1 failure in 33 launches.

After building 44 GPS satellites, Rockwell lost the “replacement” contract to General Electric Astro Space (formerly RCA Astro Electronics, currently Lockheed Martin Commercial Space Systems). The Block IIR satellites were based on the Astro Space series 4000 geosynchronous communications satellite. The 1989 contract was for 21 satellites. Many improvements in cost, lifetime, autonomy, and improved precision were made on the IIR series.

In 1997 the Air Force awarded a contract for six GPS satellites and 27 options to Rockwell (now Boeing). In 2000 the decision was made to rebid the contract. A series of studies for a “generation after next” system, Block III, was begun in 2000. This was revised in 2003 and again in 2005. The competitors are Lockheed Martin (Block IIR) and Rockwell (Block I, II, IIA).

Civilian Use

The decision to allow Transit use by commercial ships seems to have been made at an early date. This was given extra urgency when the supertanker \textit{Torrey Canyon} ran aground on the Cornish coast in March 1967, spilling 120,000 tons of oil.\textsuperscript{14}

By 1995, civilian use of GPS exceeded military use. Ten years later, GPS was the established navigation system—an “international utility.” Most other navigation systems were in the process of shutting down. But GPS remained a military system: use could be denied during a military emergency. The U.S. Federal Aviation Administration (FAA) started a program in 1995 called the Wide Area Augmentation System (WAAS) that would facilitate use of GPS for instrument landings. This would obviate the need to build the Microwave Landing System (MLS) scheduled to replace the old Instrument Landing System (ILS). Most MLS systems in the United States have been turned off and replaced by GPS.  

As GPS replaced all previous navigation (and instrument landing) systems, many foreign countries became quite concerned that transportation safety was dependent on an American military system. In part to assuage these fears and to increase the precision of GPS, selective availability (SA)—a system that ensured lower civilian accuracy—was turned off on 1 May 2000. Somewhat earlier in 1982, the Soviet Union had launched its own navigation system, GLONASS (Global Orbiting Navigation Satellite System). The system was fully operational in 1995. Unfortunately, the collapse of the Soviet economy left Russia unable to maintain the system for several years. A planned replenishment will be complete by 2010.  

Both GPS and GLONASS are military systems that allow civilian use. The European Galileo system will be completely civilian-run by a private consortium. The four GIOVE (Galileo In-Orbit Validation Experiment) satellites will be launched by 2008. The 30-satellite operational system will be complete by 2010. Galileo will provide greater accuracy (~1 m) and will work in buildings and under trees. Galileo and GPS will be compatible.  

Societal Impact of Navigation Satellites

The original purpose of navigation satellites was to maintain the so-called balance of terror. Even if the Soviet Union had launched a first strike, the submarine-launched ICBMs (SLBMs) would have enough navigational accuracy to level most of the cities of the Soviet Union—whose positions were now well-known thanks to reconnaissance satellites. NAVSTAR/GPS gave aircraft the same navigational assurance—and accuracy to within meters, not kilometers. This improved accuracy led to GPS-guided munitions used in the Gulf Wars.  

Most surprising is the ubiquity of GPS receivers in the civilian world. These are now the primary means of navigating ships and aircraft. They are also widely used

17. Ibid.
in cars and trucks, and by hikers. Of the three applications pioneered by the military, this is by far the greatest success story. Commercial sales of GPS receivers are now a $9 billion industry.  

**WEATHER**

By the 1950s, the idea of weather satellites was beginning to surface. In 1951, RAND published “Inquiry into the Feasibility of Weather Reconnaissance from a Satellite Vehicle” and Arthur C. Clarke depicted polar and geosynchronous “metsats” in the endpapers of *The Exploration of Space*. In 1954, a tropical storm was discovered accidentally when pictures taken from an Aerobee sounding rocket were analyzed. Also in 1954, Dr. Harry Wexler, the Weather Bureau’s chief scientist, presented a paper on “Observing the Weather from a Satellite Vehicle” at the Third Symposium on Space Travel. In 1955, when the decision was made to launch a satellite during the upcoming International Geophysical Year (IGY), weather observation and radiation balance payloads were considered and eventually were flown on Vanguard and Explorer satellites.

**Polar Satellites/TIROS**

In spite of the influence of scientists such as Wexler and Verner Suomi, the first weather satellite was a product of the military. TIROS (Television Infra-Red Observation Satellite) was RCA’s losing entry in the Air Force WS-117L competition won by Lockheed in 1956. The Army was persuaded to support development of TIROS as a polar-orbiting weather satellite. The project was transferred to ARPA and eventually to NASA in 1958. The first launch was on a Delta on 1 April 1960. The satellite had two television cameras: one wide-angle and one narrow-angle (high-resolution) on TIROS-1 and -2, and both wide-angle on succeeding TIROS satellites. TIROS-8 pioneered the Automatic Picture Transmission (APT) camera system. TIROS satellites had the cameras mounted on the base of the satellite, aligned with the spin axis. This meant that the cameras were Earth-pointing for only a small fraction of their orbits. TIROS-9 pioneered the “cartwheel” configuration wherein the cameras were mounted on the sides of the spacecraft; the spacecraft spin axis was aligned with orbit normal and pictures were taken continuously. All launches were from Cape Canaveral into high-inclination (481°) orbits until TIROS-9 and -10 were launched into Sun-synchronous (SS) polar orbits. Sun-synchronous orbits allowed pictures to be taken at the same local time every day (usually early morning).

The Pentagon recognized the disadvantages of the TIROS baseplate-mounted cameras and the advantages of Sun-synchronous orbits. Joseph V. Charyk, director of the National Reconnaissance Office (NRO), concluded that NASA development of a better weather satellite (Nimbus) would be delayed and expensive. He also was uncomfortable with the international commitments NASA had made to share TIROS weather pictures. Weather information was critical to NRO—too many spy satellite pictures showed nothing but clouds. In 1961, Charyk sponsored what was to become the Defense Meteorological Satellite Program (DMSP). The program envisioned an improved RCA TIROS launched on a Scout launch vehicle from Vandenberg Air Force Base. The satellite was much lighter than TIROS and carried a single television camera that would “snap” pictures of Earth when the horizon sensors indicated that the camera was pointed in the appropriate direction.

At about this time, it was decided that the next-generation civilian weather satellite, TOS (TIROS Operational System, also known as ESSA) would be a copy of DOD’s DMSP Block 4A rather than the NASA Nimbus, which became a research vehicle and later the model for ERTS/Landsat. The Block 5 satellites were three-axis-stabilized rather than spin-stabilized. A variant of Block 5 became the civilian ITOS (Improved TOS, also known as National Oceanic and Atmospheric Administration [NOAA]). The DMSP program remained classified until late 1972, when DMSP data were routinely delivered to the Weather Bureau.

The military and the intelligence community were the initial sponsors of weather satellites. NASA took over part of this remit, and by the mid-1960s the Weather Bureau (ESSA, then NOAA) took responsibility for polar weather satellites. Geostationary weather satellites seem to have been championed by NASA and transferred to the Weather Bureau almost immediately after their launch in the 1970s. The military and the intelligence community retained a separate polar weather satellite program into the twenty-first century, but a single National Polar Orbit Environmental Satellite System (NPOESS) is in the works—amid much disarray.

Geosynchronous Weather Observation

In spite of Arthur C. Clarke’s work, NASA (and Hughes) first looked at geosynchronous orbit (GEO) as a place for weather satellites, not communications satellites. A consequence of the stationary orbit over the equator was that a GEO weather satellite could take continuous pictures of about one-third of Earth’s surface. The polar weather satellites only took one picture (two if we include night-time IR pictures) of a given location each day.

In 1965, Verner Suomi and Robert Parent started the Space Science and Engineering Center (SSEC) at the University of Wisconsin-Madison with funding from NASA and the National Science Foundation. While at SSEC, Suomi developed the spin-scan camera. SSEC’s spin-scan camera was launched on ATS-1 in 1966. The camera scanned an east-west strip of Earth with each rotation of the spinning satellite. By tilting a mirror in the camera slightly at each rotation, a multi-strip image of Earth could be created in less than 30 minutes.

The NASA Applications Technology Satellites (ATSs) had originally been conceived as Advanced Syncom satellites. The creation of the Communications Satellite Corporation (Comsat) following the Communications Satellite Act of 1962 led to suggestions that communications satellite R&D by NASA was inappropriate as Comsat was a private entity. NASA was more than willing to add a meteorological payload, and DOD asked that gravity gradient stabilization and medium Earth orbits (MEOs) experiments also be conducted.

The first five ATS satellites were all built by Hughes. None of the gravity gradient experiments worked. All of the cameras worked, as did all of the C-band transponders. ATS-1 (7 December 1966) and ATS-3 (6 April 1967) were complete successes, taking the first black-and-white (ATS-1) and first color (ATS-3) pictures of Earth from geosynchronous orbit. The first three ATS launches were on Atlas-Agenas (A-As), the second two on Atlas-Centauras (A-Cs), and the sixth on a Titan. ATS-1 and -3 were deactivated in 1978. ATS-5—a nominal failure—provided communications services for many years.

The experimental/operational Synchronous Meteorological Satellites (SMSs) were built by Ford Aerospace. Their lighter weight allowed use of the cheaper, more reliable Delta launch vehicle. All carried a Visible Infrared Spin Scan Radiometer (VISSR) built by Hughes Santa Barbara Research Center. SMS-1 was placed over the Atlantic (17 May 1974) and SMS-2 was placed over the eastern Pacific (6 February 1975).

The Geostationary Operational Environmental Satellites (GOES)-1 through -3 were identical to the SMS-1 and -2 satellites. GOES-4 through GOES-7 were built by Hughes. The more advanced GOES-8 through GOES-12, (again built by Ford, now Space Systems Loral) have an imager much like the Advanced TIROS-N polar-orbiting satellites. Attitude control is three-axis and detailed position and pointing are obtained using the VHRR imager. As with the polar satellites, GOES now combines operational capabilities and research capabilities. One satellite is usually positioned over the Atlantic at 75°W (GOES-East) and another at 135°W (GOES-West). Early in the program satellites were placed over the Indian Ocean to provide “global” coverage for the Global Atmospheric Research Program (GARP). European, Indian, and Russian satellites now provide Indian Ocean coverage while Japan provides coverage of the western Pacific. Any “extra” GOES satellites are stored at 105°W—ready to replace GOES-East or GOES-West.
International Cooperation

Meteorological data have always been shared with other countries. In 1977 both Europe and Japan launched geosynchronous orbit weather satellites. When the GOES-NEXT program was delayed, the Europeans loaned NOAA a Meteosat. When the Japanese MTSAT was delayed, NOAA loaned the Japanese Meteorological Agency (JMA) a GOES. Starting from the prime meridian, Eumetsat covers the eastern Atlantic from 0°E and the Indian Ocean from 62°E. JMA covers the western Pacific from 140°E (and 155°E). NOAA covers the eastern Pacific from 135°W and the western Atlantic from 75°W. The five satellites of these three agencies continuously monitor Earth’s weather, except for polar latitudes. These countries also cooperate by sharing polar weather data; Russia also supports this activity.

Societal Impact of Weather Satellites

The major U.S. hurricanes of 1900 and 1938 came from nowhere and killed people on the shoreline who had no idea a major storm was coming. On 8 September 1900, Galveston, Texas, had a population of about 36,000; by nightfall, one in six would be dead. The 1938 New England hurricane completely wiped out several vacation areas and flooded sea-level Providence, Rhode Island, and interior Hartford, Connecticut. The Galveston Hurricane of 1900 may have been the deadliest natural disaster in the United States but it does not even appear on any list of storms sorted by damage cost. In contrast, Galveston was evacuated over the single bridge linking it to the mainland before Hurricane Rita hit in September 2005. Evacuation was probably easier to enforce after the Hurricane Katrina disaster a month earlier. Katrina was among the most costly hurricanes to hit the United States but the death toll—in spite of poor evacuation plans—was much lower than it might have been. The inflation-adjusted cost of Katrina damage was 100 times the cost of the 1900 Galveston hurricane damage but the death toll was one-third. NOAA predicted landfall at New Orleans more than two days in advance, and the day before landfall the local NOAA office recommended immediate evacuation. Weather satellites don’t just provide cloud pictures and warnings of hurricanes. They also detect forest fires, volcanic activity, and severe storms, and provide measures of rainfall and winds. Somewhat surprisingly, the value of weather satellites for forecasting is much less clear than the value for severe weather detection and monitoring.  

The commercial value of weather satellites was demonstrated in the mid-1980s when the Reagan administration was trying to privatize Landsat. Comsat offered to take over Landsat only if it was also given the weather satellites. NOAA has provided a compendium of economic statistics in which the costs of weather and climate events are summarized along with some estimates of the benefits of weather forecasting. Severe weather causes damages well in excess of $10 billion every year. Total benefits

to the householders are estimated at over $10 billion per year. Benefits to agriculture, construction, and transportation would presumably increase this total.\textsuperscript{23}

**COMMUNICATIONS**

Although several pre–World War II mentions of satellite communications have been found, the first well-known discussion was Arthur C. Clarke’s 1945 article in *Wireless World*.\textsuperscript{24} Perhaps of greater importance were later articles by John R. Pierce in *Jet Propulsion* (1955) and *Proceedings of the IRE* (1959).\textsuperscript{25} Clarke was a member of the British Interplanetary Society and a budding science-fiction author. Pierce was also a science-fiction author but, more importantly, he was the director of communications research at AT&T’s Bell Telephone Laboratories (BTL).

In early March 1958,\textsuperscript{26} John R. Pierce and Rudolf Kompfner of AT&T (independent inventors of the traveling-wave tube) saw a picture of the shiny, 100-foot sphere that William J. O’Sullivan of NACA Langley Research Center was proposing to launch into space for atmospheric research. It reminded Pierce of the 100-foot communications reflector he had envisioned in 1954. Pierce persuaded William H. Pickering of JPL to provide a West coast antenna for the experiment. To support this plan, Kompfner and Pierce wrote a paper\textsuperscript{27} that they presented at an IRE conference on “Extended Range Communications” at the Lisner Auditorium of George Washington University in Washington, DC, on 6–7 October 1958.\textsuperscript{28}

Echo I was launched into a 1,000-mile circular orbit on 12 August 1960. During the first orbit of the 100-foot sphere, a recording of President Eisenhower speaking was transmitted from JPL’s Goldstone, California, Earth station to AT&T’s Holmdel, New Jersey, Earth station. In spite of Echo’s success, it was clear that active, rather than passive, satellites were the technology to develop.\textsuperscript{29} In a 13 May 1960 letter to Leonard Jaffe at NASA Headquarters, Rudolf Kompfner had described the current AT&T/BTL research program as shifting to active satellites. In this letter Kompfner reviews the active satellite component/subsystem studies that had been underway since late 1959.\textsuperscript{30}

\textsuperscript{24} Arthur C. Clarke, “Extra-terrestrial Relays.”
\textsuperscript{27} Pierce and Kompfner, “Transoceanic Communications by Means of Satellites.”
By 1960, Pierce had convinced AT&T management to build and launch a medium-earth-orbit (MEO) satellite system. Even earlier, the Pierce and Kompfner paper had also energized a group of young engineers—Harold Rosen and Donald D. Williams—at Hughes Aircraft Company to prove wrong their 1959 argument that geosynchronous Earth orbit (GEO) satellites were beyond the state of the art. AT&T’s plan to launch a satellite system was put on hold when NASA refused to provide launch services. NASA argued that launch vehicles were in short supply and must be rationed. The rationing mechanism would be a competition to design a MEO communications satellite. Proposals were submitted to NASA by seven companies—including Hughes (Syncom) and AT&T (Telstar). RCA won the competition for the Relay satellite in May 1961, but AT&T was allowed to purchase launch services and the Hughes satellite was jointly funded by NASA and DOD by the end of that summer.

On 10 July 1962, at 8:25 UT (4:25 a.m. EDT) the Delta carrying Telstar 1 lifted off from its pad at Cape Canaveral. AT&T had placed a commercially funded communications satellite in orbit before the government-funded projects, but the Communications Satellite Act would be passed less than two months later. AT&T, after expending more than $100 million (in 1960 USD) was out of the satellite manufacturing business for good. The NASA/RCA Relay (MEO) and the Hughes/NASA Syncom (GEO) satellites would be launched over the next two years.

The Communications Satellite Act of 1962

Just after NASA’s announcement of the Relay communications satellite program award to RCA, President John F. Kennedy delivered a speech to Congress on “Urgent National Needs.” In this famous 25 May 1961 speech, Kennedy promised to land a man on the Moon and also asked the Congress to provide the funds that “will make the most of our present leadership, by accelerating the use of space satellites for worldwide communications.” This speech has been characterized as being driven by the unfortunate events of April 1961—Gagarin’s orbital flight and the Bay of Pigs—but his comments echo the Wiesner committee’s “Report to the President—Elect of the Ad Hoc Committee on Space,” delivered to Kennedy on 10 January 1961.31 It is also consistent with his State of the Union message of 30 January 1961:

Finally, this Administration intends to explore promptly all possible areas of cooperation with the Soviet Union and other nations “to invoke the wonders of science instead of its terrors.” Specifically, I now invite all nations—including the Soviet Union—to join with us in developing a weather prediction program, in a new communications satellite program and in preparation for probing the distant planets of Mars and Venus, probes which may someday unlock the deepest secrets of the universe.32

In any case, politics—cold war politics—would be a driver in deployment of communications satellites.

The Space Council drafted an Administration Bill in November 1961 providing for a public-private corporation directly regulated by the president. Before it was submitted, Senator Robert Kerr (D-Oklahoma) submitted a similar bill that gave more control to the international communications carriers—as the FCC recommended. Another bill was introduced by Senator Estes Kefauver (D-Tennessee) that advocated government ownership. The Administration Bill passed the House 354 to 9 and, after a liberal filibuster, passed the Senate 66 to 11. On 31 August 1962, President Kennedy signed the bill into law.

The Interim Agreements

Comsat had been advised by the common carriers—especially AT&T—that bilateral arrangements between Comsat and each of the foreign post, telegraph, and telephone (PTT) organizations were preferable. Even as bilateral negotiations were being considered and before the incorporators had met, a U.K., Canada, and U.S. (Foreign Ministry/State Department) conference on satellite communications took place in Washington. In October of 1963, the International Telecommunications Union (ITU) held an Extraordinary Administrative Radio Conference (EARC) in Geneva to discuss frequencies for satellite communications. Somewhat to their surprise, Comsat got almost everything they wanted out of the conference. 33

Comsat, and later Intelsat, had a major problem: Were they “commercial” entities, in the limited sense that government-owned PTTS were “commercial,” or were they instruments of foreign policy? If they were commercial entities, then their purpose was to earn a profit for their owners by providing global satellite communications. If they were profit-oriented, then decisions should be based on costs and profits. For a long period, purchase of American satellites by Comsat and Intelsat was based on the cost-benefit analysis that these showed these satellites would provide the best service—and hence greatest profits—at the lowest cost. If Intelsat and Comsat were instruments of foreign policy, however, then profits were irrelevant. If these organizations were instruments of technological advance, then each country should obtain “work” (manufacturing contracts) in proportion to their contribution of funding. This later became the European Space Agency’s (ESA’s) principle of juste retour.34

In early 1964, the United States (the State Department and Comsat) met with the Europeans in Rome. It was clear at this meeting that the Europeans would insist on some amount of control over satellite communications. The next meeting was in London with additional participation. At this meeting it became obvious that

34. Ibid.
there would be two agreements: a government-to-government agreement and a PTT-to-PTT agreement, with Comsat as the American PTT. The final version of the interim agreements was presented to the world on 20 August 1964 in Vatican City, where 14 countries immediately signed it. It is interesting to note that during this negotiation process, Comsat contracted for the geosynchronous Early Bird and raised $200 million in an initial public offering (IPO).35

The three most important consequences of this interim agreement were: (1) Comsat would not go it alone, but it would manage the interim system under an Interim Communications Satellite Committee (ICSC); (2) the organization would have both Foreign Office and PTT representation; and (3) a new definitive agreement would be negotiated in five years.36

**Early Bird and Intelsat-II**

Early Bird was launched in April 1965 and entered service in June. A few months later, the interim organization adopted the name Intelsat. Four Intelsat II series satellites were launched in 1966–1967; three were successful. The Intelsat II series was launched to support NASA’s Apollo program. Early Bird covered only the northern hemisphere over the Atlantic Ocean Region (AOR). The Intelsat II series covered the globe and were located over both the AOR and Pacific Ocean Region (POR).

**The Intelsat Definitive Agreements**

When it came time to meet in February 1969 to discuss the definitive arrangements, the old disagreements were still present. The ICSC, representing the Intelsat consortium, had been dominated by Comsat. The first Plenipotentiary Conference was held from 24 February to 21 March 1969 in Washington. All but one of Intelsat’s 68 member states sent a delegation. Some indication of where things might be headed was the reception that Katherine Johnsen of *Aviation Week & Space Technology* got when she tried to interview the members of the ICSC in 1967: 17 agreed to be interviewed; only John A. Johnson refused. Similarly, at an ICSC meeting in December 1968, a vote was taken as to whether Comsat should remain as manager: the result was 17 to 1 against.37

The third and final Conference on Definitive Agreements began on 14 April 1971. On 20 August 1971, the Agreements were opened for signature and by 14 December 1972 two-thirds of the members had signed. Sixty days later, on 12 February 1973, the interim agreements were terminated and the new agreement entered into force.38

35. Ibid.
37. Katherine Johnsen, “France Backs UN Intelsat Control,” *Aviation Week & Space Technology* (13 February 1967); Maddox, Babel, pp. 103-104.
The strange public-private, commercial-political nature of Comsat was also reflected in the structure of Intelsat. Intelsat had two “governing bodies”: nations signed the Intelsat Agreement (also referred to as the Intelsat Treaty), but telecommunications entities (signatories) signed the Intelsat Operating Agreement. The Intelsat Assembly of Parties consisted of the sovereign governments that signed the Intelsat Agreement. Voting in the Assembly was by country: one nation—one vote. Its powers were limited. The Meeting of Signatories consisted of all the telecommunications entities that signed the Intelsat Operating Agreement. Voting in the meeting was on the basis of shares and the shares were allocated (and paid for) on the basis of usage. This has been referred to as “one telephone call—one vote.” A board of governors had functions similar to the ICSC, or to the functions of a commercial board of directors. The Board consisted of about 20 members, each having a minimum specified investment, and individual representatives of member-groups whose total investment met the minimum specified (about 2 percent). Finally, there was a manager (Comsat for six years after the agreements enter into force, terminating on 12 February 1979), reporting to a secretary general until 31 December 1976 and to a director general thereafter.

The major antagonists, the United States and the Franco-Europeans, each compromised in some way but the result was both semi-commercial and semi-political. It could be argued that the State Department got what it wanted because the third-world countries wanted international communications at reasonable rates and with some national control—at least control of their own Earth stations. The Europeans continued to complain that satellite contracts went exclusively to the United States (until the 1990s), but the third-world countries preferred cheaper, higher-quality American satellites and launch vehicles.

Intelsat III and IV

Comsat had not officially chosen geosynchronous orbit when the Intelsat III contract was put out for bids. Hughes decided not to bid an MEO option. This allowed TRW to sneak in a winning bid. These satellites were the first to provide coverage of the Indian Ocean Region (IOR). Almost in parallel to the Intelsat III program was the Intelsat IV program. The first three generations had relatively limited capacity. Intelsat IV would be a significant increase in power, number of transponders, mass, and coverage options. The first three generations had Earth coverage only. Intelsat III was considered a big advance because it had a despun antenna that always pointed at Earth—dramatically increasing equivalent isotropically radiated power (EIRP). Intelsat IV had two narrowbeam antennas covering the East and West hemispheres. Because of its size, this series would use the Atlas-Centaur launch vehicle instead of the Delta. About 20 percent of the content was provided by international manufacturers.

It was no surprise when Intelsat discovered that North Atlantic traffic (AOR) was greater than POR or IOR. Intelsat IVA F6 was the last satellite launched by Comsat as Intelsat “manager.” The definitive agreements left them without a major role in satellite development. Comsat still monitored construction under contract to Intelsat, but executive decisions were made by Intelsat.
Domestic Satellite Communications

Neither the Communications Satellite Act of 1962 nor the Interim Intelsat Agreements precluded domestic communications satellites (domsats). It was assumed—and later made explicit—that domsats should not interfere with Intelsat. A small working group was put together in 1969 to formulate Nixon administration domsat policy. Among the members of the group was Clay T. Whitehead. Whitehead’s boss, Peter Flanigan, sent a memo to Dean Burch at the Federal Communications Commission (FCC) recommending open entry—“open skies”—on 23 January 1970. Thirteen entities had already filed for authorization to launch domsats. In March 1972, the FCC released a proposed Second Report and Order on DOMSATs, requesting that the filers consolidate their filings. Nobody liked this. The actual Second Report and Order was released on 16 June 1972 after a 4 to 3 vote by the commissioners. The dissenters objected to the restrictions on AT&T and Comsat. A final Report on DOMSAT was issued 22 December 1972 modifying (but retaining) these restrictions.

Meanwhile, Canada had quickly decided to launch a Canadian satellite to service the Far North. In 1967, the Chapman Report recommended that a satellite system be developed. In 1969, Telesat Canada was established. On 9 November 1972, Anik A1—a Hughes HS-333—was launched on an American Delta launch vehicle. RCA Global Communications began service to Alaska on Anik. RCA may have been first into service, but Western Union (the telegraph company) was the first U.S. company to launch its own satellite (13 April 1974).

RCA built its own satellite using the services of RCA Astro-Electronics in East Windsor, New Jersey and RCA Canada (later Spar) in Montreal. The RCA satellites had twice the number of transponders and twice the power of the HS-333. They were the first operational (as opposed to the experimental ATS-6 and Symphonie) three-axis-stabilized communications satellites.

AT&T had built its own experimental Telstar satellites but opted to buy Hughes satellites for its operational program. More accurately, it leased satellites from Comsat. AT&T was constrained to provide only point-to-point services—they could not offer television distribution services.

Indonesia was the third nation to launch a commercial geosynchronous communications satellite business. The Palapa series, like Anik and Westar, was based on the HS-333. Within a few years of the first launch, the tens of thousands of Indonesian islands were connected via satellite.

The Television Revolution

The original U.S. filing for a domestic communications satellite had been made in 1965 by ABC with encouragement from Hughes. Comsat and Intelsat had never been much interested in television—some at Comsat argued that only four television transponders were necessary, one for each network (ABC, CBS, NBC, and educational television). Some at RCA (owners of NBC) argued that at least 20
transponders were needed—one for each of the four networks in each of the three
time zones plus one for each NFL game. Although a few had seen the future, the
explosion in television, especially non-network cable television, was a shock. Within
a few years there were a dozen satellites carrying more than 200 transponders. Two­
thirds of the traffic was television—a ratio that persists to this day. By the 1990s
in the U.S. (earlier in Europe) dedicated direct-to-home broadcast satellites had
revenues in the tens of billions of dollars.

**COMSAT AND INTELSAT: COMPEITION AND OTHER PROBLEMS**

Comsat was looking for a mission after 1979. The company tried domestic
satellites (Comstar with AT&T, SBS with IBM), broadcast satellites (STC), software,
ground systems, and especially Earth stations (RSI). None of them worked. By
the mid-1980s the company’s profits were bouncing up and down. It seemed that
every other year the company lost tens of millions of dollars. Intelsat did well in
these years, and it was still the largest and most profitable satellite company. It had
few business barriers because its owners were the national PTTs. In the late 1980s
competition did begin to affect Intelsat. More dangerous was the fact that the U.S.
government was seeking to destroy its monopoly.

There had long been concerns that Comsat/Intelsat was a monopoly and monopolies
are “bad.” On 28 November 1984 President Reagan announced that “separate systems”
were required in the national interest. Based on the president’s decision, the FCC began
granting conditional licenses. On 25 July 1985 the FCC issued its Separate Systems
Report and Order. On 1 June 1988 PanAmSat’s PAS-1 was launched and eventually
drifted to a longitude of 45°W to provide trans-Atlantic service.

That same year, the fiber-optic TAT-8 cable began to provide service across
the Atlantic—service that was cheaper than Intelsat. The trans-Atlantic telephone
cables had always competed with satellite transmission across the Atlantic but the
savings, if any, were minimal. Fiber-optic cables were cheaper, provided higher­
quality transmissions, and much higher data rates.

**Comsat and Lockheed**

How did it all begin? In 1995 Lockheed and Martin Marietta merged. The earlier
combination of RCA Astro and GE Space that had been purchased by Martin Marietta
became Lockheed Martin Commercial Space Systems (LMCSS). Martin Marietta had
been looking at getting into communications satellite operations rather than (or in addition
to) manufacturing. Profit margins in manufacturing looked slim compared to operations.

By early 1998, it seemed clear that Comsat was on the market. Early in the
year, Comsat denied that it was being acquired by Loral.39 In July, fallout from the
Cox Report caused aerospace stocks to tumble: Comsat fell to $28.75 from $42

over a “couple months.” Comsat claimed it was in the process of “unlocking the value of investments in Intelsat and Inmarsat.” On September 20, Lockheed (LMT) announced plans to purchase Comsat after failing to buy Northrup Grumman for $8.3 billion. The Lockheed offer was for 49 percent of the Comsat stock at $45.50 per share with the last 51 percent to be purchased, with one share of Lockheed for two shares of Comsat. The total value of the purchase was about $2.7 billion. The Lockheed offering of $45.50 was about one-third higher than the market price $341/8. Comsat was apparently vulnerable to takeover due to its small size. Lockheed shares fell while Comsat shares climbed.41

On August 20, 1999 Comsat shareholders voted to accept LMT’s offer (99 percent of votes, 74 percent of shares). The plunge in value of Lockheed shares reduced the value of the deal from $2.7 billion to $2.2 billion.42 On September 15 the FCC authorized Lockheed to purchase 49 percent of Comsat. Lockheed was also authorized to buy Comsat Government Services, Inc. (CGSI). In addition to buying 49 percent of the shares at $45.50 per share, the remaining 51 percent would be a share-for-share deal (Lockheed had split). Lockheed would also assume $455 million in Comsat debt.44 On September 16, the Department of Justice authorized the Lockheed-Comsat merger.45

The Orbit Act of 2000

In 1996 the U.S. Government Accountability Office (GAO) made a report to Congress, requested by Thomas J. Bliley, Jr. (R-Virginia), on Intelsat restructuring. In 1997 Bliley and Edward J. Markey (D-Massachusetts) submitted a bill (H.R. 1872) to privatize Intelsat and Inmarsat.47 On 30 July 1997 Senator Conrad Burns (R-Montana) and his Communications subcommittee held hearings on “Satellites and the Telecommunications Act.” The FCC, NTIA, and State Departments testified, as did Intelsat, PanAmSat, and Comsat.48 The claim was made that Comsat’s markup on

43. “FCC Authorizes Lockheed Martin to Purchase up to 49 Percent of COMSAT,” FCC News (15 September 1999).
Intelsat pricing was as much as 86 percent. On 25 March 1998, the House committee passed the Biley bill (H.R. 1872), including “direct access” and a variant of “fresh look.” “Direct access” allowed customers to deal directly with Intelsat—bypassing Comsat. “Fresh look” afforded customers an opportunity to renegotiate all Comsat-mediated contracts for Intelsat bandwidth. Intelsat’s Tony Trujillo commented that the bill was fatally flawed. Nevertheless, H.R. 1872 passed the entire House on 6 May 1998.

The House bill provided for both “direct access” and a variant of “fresh look.” Sen. Burns introduced a different bill (S. 2365) on July 29, a bill seen as more favorable to Comsat. PanAmSat claimed that S. 376, the Open-Market Reorganization for the Betterment of International Telecommunications (ORBIT) bill did not go far enough. On January 21, Tom Biley asked the FCC to reject any ownership greater than 10 percent until after the passage of reform legislation. On 5 May 1999, the full Senate committee approved the ORBIT bill (S. 376). On July 1, the ORBIT bill was passed unanimously by the Senate. “Fresh look” was not allowed, but “direct access” was. Tony Trujillo of Intelsat described the bill as “the heavy hand of the U.S. Congress.” Senator Lott insisted that Burns allow “direct access” by 1 July 2002. The Biley House bill passed in 1998 had removed almost all Comsat privileges.

On February 17 the House and Senate conference committee reached a compromise. Direct access was allowed and the Intelsat IPO was delayed to 1 January 2003. On April 4, an FCC Public Notice was published to the effect that LMT had applied to transfer control of Comsat to LMT/CGS. On July 31 the FCC authorized Lockheed to merge with Comsat based on the provisions of the 17 March 2000 ORBIT Act.

The End of Comsat

Lockheed Martin Global Telecommunications (LMGT) did not last long. On 7 December 2001 (the 60th anniversary of Pearl Harbor), LMGT announced

that it was shutting down its operations. Some units would be absorbed by other 
Lockheed divisions, some units would be sold off, and some units would simply 
disappear. Earlier that year, much of Comsat Laboratories was sold to ViaSat. In 
January 2002 the sale of Comsat Mobile Communications to Telenor had been 
finalized. In March 2002 Lockheed sold its remaining Comsat World Systems 
facilities to Intelsat. Finally, in 2004 Comsat General’s remaining facilities were also 
sold to Intelsat by Lockheed. The public–private experiment was over.

Merger with PanAmSat

After the dot-com crash and general telecom meltdown of the early twenty-first 
century, market share and profitability became critical. On 28 August 2005 Intelsat 
and PanAmSat agreed to merge. The merger of the second- and fourth-largest fixed 
service satellite (FSS) companies would produce a giant that owned between a quarter 
and a third of all FSS satellites. What makes this merger particularly strange is that 
PanAmSat was formed as “the non-Intelsat” by René Anselmo in 1984. The PanAmSat 
motto was “Truth and technology will triumph over bullshit and bureaucracy.” René 
despised the Comsat–Intelsat monopoly. The PanAmSat mascot was the dog Spot— 
usually seen urinating on the leg of a representative of bullshit and bureaucracy.

Intelsat agreed to buy PanAmSat Holding Corp. for $3.2 billion in cash. The 
merged companies would form the world’s largest satellite company and give the 
companies a more diversified set of businesses. The new company would own 53 
satellites spanning the globe and generate annual revenues of more than $1.9 billion.

On 7 July 2006, the $6.4-billion purchase of PanAmSat was completed, creating 
a merged company carrying one-quarter of the world’s commercial satellite-delivered 
television programming. The acquisition leaves PanAmSat a wholly owned subsidiary 
of Intelsat. The combined company would initially lose money. PanAmSat earned 
$72.7 million in 2005 but Intelsat lost about $325 million. Intelsat chief executive 
David McGlade told The Washington Post that, given the level of debt and interest 
payments, the company did not expect to become profitable in the foreseeable 
future. He said the company’s investors have been pleased with Intelsat’s positive 
cash flow and its heavy backlog of orders. The traditional core of Intelsat’s business 
has been telephony, a difficult market in recent years. The combined company will 
be more diverse with the addition of PanAmSat’s television customers.58

Societal Impact of Communications Satellites

Revenues for commercial satellite applications have been dominated by satellite 
communications.59 This industry has yet to attain the $100 billion estimated in the

59. Much of the material for this section comes from the Satellite Industry Association and Futron. 
early days, but total revenues are approaching this figure ($88.8 billion according to SIA/Futron). The fixed (FSS), mobile (MSS), and broadcast (BSS) satellite service sectors had revenues exceeding $50 billion in 2005. Direct broadcast satellite (DBS) revenues led at $41.3 billion, followed by FSS revenues at $9.8 billion and MSS revenues at $1.7 billion.

**Some Final Thoughts**

The first space application to be operationalized was remote sensing with the launch of the first Discover on 28 February 1959. One could argue that “success” wasn’t achieved until August 1960 but, in any case, this was the first application where significant funds were expended. These funds came from DOD (Air Force) and the intelligence community (CIA). Neither NASA nor commercial firms were involved except as manufacturers or other contractors. Although NASA launched the first Earth Resources Technology (ERT)/Landsat satellite in 1972, it is not clear that remote sensing has ever been truly commercialized, although one can argue that by the twenty-first century it was possible to buy fairly high-resolution imaging on the open market.

The second space application to be operationalized was navigation with the launch of the first Transit on 17 September 1959. Transit funding came from DOD (Navy), as did funding for GPS/NAVSTAR (Air Force) later. In 1967, Transit use by the civilian maritime industry was allowed. Although funding for the satellites has come exclusively from DOD, this application has definitely been commercialized, as evidenced by the billions of dollars expended every year for GPS receivers.

The third space application to be operationalized was weather with the launch of the first TIROS on 1 April 1960. TIROS was based on the RCA proposal for a reconnaissance satellite. Initial funding came from the Army but the project was transferred to NASA. NASA funded TIROS and many of its upgrades, although many of these upgrades were initially funded by DOD on the DMSP program. The Weather Bureau eventually began funding operation of the satellites and, somewhat later, satellite procurement. NASA seems to have taken the lead on geosynchronous weather satellites, launching the first Synchronous Meteorological Satellite (SMS-1) in 1974. Commercialization of this application probably started with the launch of TIROS-1, but transfer to the Weather Bureau (ESSA) didn’t formally occur until TOS in 1966.

The fourth space application to be operationalized was communications with the first launch of Telstar on 10 July 1962. Earlier dates (Courier and Echo in 1960) and later dates (Syncom 2 in 1963) can be proposed, but it is fascinating to observe that the most commercial of all space applications was the last to be actually launched. Not surprisingly, it was the first to be commercialized—in every sense of that word—when Early Bird was launched on 6 April 1965. Funding for the earliest communications satellites is complicated. By far the largest investor was AT&T but much of that investment was for manufacturing capability. NASA was the second-
largest investor, funding most of Syncom and all of Relay. Hughes was the third-
largest investor and may have gained the greatest profit by building proto-Syncom
with its own funds.

Communications satellites showed the most interesting behaviors, possibly
because they are so commercial. The failures—Aerosat, SBS, STC, the LEOs, and the
MEOs—all seemed to have misread the market for their offerings. The international
projects (Inmarsat and Intelsat) seemed to have generated geopolitical hassles. Others
have had trouble generating profits, such as DARS and, to a lesser extent, DTH TV.

It is interesting to note that the earliest space applications are the ones
developed by or for DOD (reconnaissance and navigation). It should be no
surprise that the most commercial of all the applications (communications) shows
the greatest commercial funding and the earliest commercialization. The role of
NASA is hard to evaluate. NASA seems to have been more of a facilitator than
anything else. NASA had no real part in reconnaissance and navigation but certainly
“facilitated” the development of weather satellites. It is also possible to claim that
NASA “facilitated” the development of communications satellites. If NASA had
not been involved, AT&T would have gone ahead with its MEO Telstar system.
This might have made it very difficult for the Hughes “better idea” to make it into
a marketplace that was dominated by AT&T. It would be interesting to examine
the effect on NASA priorities of its R&D agency status. Any application developed
by NASA would have to be given away. Perhaps one measure of NASA’s influence
would be to examine what would have happened without NASA. Reconnaissance,
navigation, and communications satellites would have been developed by DOD
and industry, but the weather story is more complicated. DOD did not want their
weather pictures circulated; DMSP is proof of this. It is not clear that the Weather
Bureau would have invested the funds that NASA made available. NASA is still
supporting development of weather satellites.

Applications satellites are not as glamorous as Moon landings—or Mars
landings—but they have made a huge difference in the world we live in: financially,
culturally, and in the areas of safety and security. They have created the global village.
It is a feisty, angry, violent village, but there are fewer unknowns and a greater
chance for peace and prosperity.
Chapter 16

NASA and the Environment: Science in a Political Context

W. Henry Lambright

The advent of the Space Age has paralleled the rise of the environmental movement. NASA was born in 1958 and Rachel Carson wrote *Silent Spring* in 1962; that book is generally seen as marking the onset of modern environmentalism.\(^1\) NASA has intersected with the environmental movement—a set of values and interest groups concerned about the need to protect our natural setting for the current and future generations—in many ways over the years. How did NASA do so? How did it evolve an environmental mission? What did it do with that mission? What were the consequences for society—and NASA—of its environmental role? To answer these questions, this paper will discuss two of the most important ways NASA and the environmental movement related.

First, NASA has had direct impacts through the images of Earth taken by Apollo astronauts as well as by satellites in Earth orbit. Those satellite images and theories about Earth as a system evolved into an organized NASA program, initially called Mission To Planet Earth (MTPE), later the Earth Sciences Program. Second, there was an indirect relation through NASA’s mission from Earth. Comparative planetology came into existence as a new field; learning about other planets stimulated better understanding of Earth.

There are many other issues in the NASA–environment relation, such as space debris and the contamination of other planets, but these two themes—Earth monitoring and comparative planetology—are especially salient in NASA’s history, present, and likely future. The first theme focused on the use of space-based remote sensing and became the dominant emphasis in NASA’s environmental history.

---

\(^1\) The author wishes to thank NASA for support for this paper’s research and also Sara Pesek for research assistance. Ms. Pesek was a Master of Public Administration graduate student at the Maxwell School of Syracuse University.

There evolved a set of satellites that can be seen as environmental satellites. They are the centerpiece of NASA’s mission to Earth. That mission has had an uncertain, somewhat uneasy relationship with other parts of NASA and other agencies. Some people think it is NASA’s most societally relevant mission whereas others think it is extraneous to NASA and belongs somewhere else—the National Oceanic and Atmospheric Administration (NOAA) is the usual candidate. Virtually every observer has found it a controversial mission, one in need of high-level policy attention and improvement for the sake of NASA, the nation, and the world.

The second theme, comparative planetology, has indirectly influenced the main debate—a reminder of the fact that Earth is an island home in the vast sea of space and is the only planet (so far) supporting life. NASA’s long association with the environmental and Earth sciences has been fruitful but it has also been contested and even tortuous. The history of NASA and its environmental mission is one of science in a political context.

**Beginnings in the Apollo Years**

In the 1960s, as NASA concentrated on the Moon project and environmentalism emerged as a conscious political and philosophical movement, NASA began to monitor aspects of the environment in the name of an “applications” program, part of NASA’s Office of Space Science and Applications (OSSA). Its chief activity was initially weather satellites. Early on, NASA negotiated a relationship with the predecessor of NOAA, the Weather Bureau, such that NASA developed weather satellite technology and then transferred it to the weather forecasting agency for operational use. The weather satellite program was clearly one of the great successes of the 1960s. It was obvious to all that weather satellites improved forecasts and aided early warnings of approaching hurricanes. There was a technology push from NASA and a pull from a user agency.3

Comparative planetology also began in the 1960s, with the Mariner spacecraft flybys of Venus and Mars. Venus revealed a runaway greenhouse effect that heated it into an inferno, providing an early example to some scientists of what could happen here. Mars also seemed inhospitable to life. But the most important impacts on the environmental movement of the early space program were pictures of Earth taken by Apollo astronauts, beginning with Apollo 8 in 1968—the Christmas Eve flight around the Moon. For the first time, humanity saw a blue Earth in the desolate blackness of space. As the environmental movement emerged, it used these images

---

of our planet as a symbol for the first Earth Day in 1970. Without a doubt, the space program helped catalyze the environmental movement, especially insofar as getting it to think about the global environment.  

**NASA in the 1970s**

The 1970s are often called an environmental decade. One reason is that Environmental Protection Agency (EPA) was born in 1970 and Congress enacted a sequence of laws to deal with water, air, and other forms of pollution. Another reason was the energy crisis of the decade, and writings on “limits to growth.” The Carter administration, in particular, integrated environment and energy conservation and conveyed the notion that “small is beautiful.” This notion was applied to technology, which environmentalists argued had to be “appropriate” to the user.

The space program in the 1970s mirrored the decade’s political setting. NASA devolved from Apollo, whose moon flights ended in 1972, to the Space Shuttle. NASA diminished in size and exploratory capacity. The NASA Administrator, James Fletcher, who served from 1972 to 1977 (the first of two terms at NASA’s helm) was personally interested in environmental stewardship, a characteristic Launius has linked in part to his Mormon roots. However, the situation he faced was problematic. The environmental movement of the early 1970s had a distinctly anti-technological flavor. It contributed to the termination of the supersonic transport (SST) in 1971. There were concerns in NASA that environmentalists might attack the Space Shuttle as they had attacked SST, on environmental factors. NASA realized that it needed to research environmental-atmospheric impacts of the shuttle to defend itself, if necessary, against possible opposition. More positively, Fletcher sought to align his Agency with environmental values. In 1973, he told Congress that NASA should be considered “an environmental agency.” He declared: “Everything we do . . . helps in some practical way to improve the environment of our planet and helps us understand the

---

5. *Limits to Growth* was the name of a best-selling book authored by Donella Meadows and others and published in 1972 under the auspices of a business group called the Club of Rome. It modeled the consequences of a world with a growing population and limited resources. It was republished in 2002 by Chelsea Green Publishing, White River Junction, Vermont.

forces that affect it. Perhaps that is our essential task, to study and understand the Earth and its environment.”

Fletcher promoted a new Earth-oriented satellite, called Landsat, launched in 1972, that was capable of helping to forecast world food harvests and other resource issues. Conscious of environmentalist concern about pollution of the stratosphere from high-flying planes that could extend to the shuttle, he sought legislation to undergird NASA’s emergent environmental (and shuttle) interests. In 1975 Congress authorized NASA “to conduct a comprehensive program of research, technology, and monitoring of the phenomena of the upper atmosphere.” In 1977, Congress required NASA to issue biennial reports to Congress on the status of ozone depletion, an issue beginning to worry some scientists and environmentalists. This legislation (1975 and 1977) was important; it gave NASA legitimacy not only to do environmental research but also to link it with policy. It was not a “given” that NASA would have this mission rather than another agency. It reflected NASA’s administrative entrepreneurship and Congressional support relative to that of potential rivals.

The 1970s also featured the growth of comparative planetology, as a field, energized by the 1976 Viking mission to Mars and James Lovelock’s Gaia Hypothesis. Lovelock, who published his ideas in 1974, held that Earth was a living system in which physical and biological components worked together to enable life. As it developed, the Gaia Hypothesis drew on studies of other planets, including Viking’s apparent failure to find life on Mars. It made a number of scientists and environmentalists better appreciate Earth as a precious and vulnerable home and the role of human beings in altering it. There even were those such as Gerard O’Neill, a Princeton physicist, who speculated that man might need to migrate beyond Earth and establish colonies in space—a new, better place, a utopia where a more eco-friendly existence could be practiced.

**The Rise of NASA’s Environmental Role in the 1980s**

The 1970s produced a set of ideas about Earth as an interacting system. Also, some scientists felt that techniques used to study Mars could be applied on Earth. The decade also gave rise to NASA’s thinking more strategically about crafting an

---

11. In 1976, when NASA sent Viking to Mars, it found the intended landing spot to be unsuitable. NASA and leading Mars specialists searched for three weeks to find a good place, surveying virtually the entire planet. At the end, Michael McElroy of Harvard declared: “You know, we’ve never done anything like this for the Earth.” Burton Edelson, “Mission to Planet Earth,” *Science*, 227, no. 4185 (25 January 1985), p. 6.
environmental mission and how better to use the legislation it had obtained for its atmospheric research. In the 1980s, NASA charted a larger and broader Earth observation program that built on its work in weather, land satellite monitoring, and initial attempts at ocean surveys. What NASA contributed, through its satellites and comparative planetology studies, was a perspective different in scale from other agencies—literally a global view. There were certain environmental issues that were indeed global in scale and NASA, in the view of some of its officials and external supporters, was particularly suited to address these.

In 1982, NASA Administrator James Beggs, responding to overtures from OSSA, went to the United Nations Conference on the Peaceful Uses of Outer Space, where he called for “an international cooperative project to use space technology to address natural and manmade changes affecting habitability of Earth.” The reaction to his “Global Habitability” overture was overwhelmingly negative—not to the idea of global habitability but to NASA as leader. “It came across like NASA was trying to take over the world,” Burton Edelson, associate administrator of OSSA, recalled. There had been no spadework ahead of time to build a coalition of support for the proposed endeavor. Beggs told Edelson to build that support base with other agencies, the White House, the scientific community, and the public before surfacing the proposal again.

This he began to do, starting in 1983 with a broad-gauged Earth System Science Committee. Edelson worked outside and inside NASA—outside with the scientific community, the National Science Foundation (NSF), and the National Oceanic and Atmospheric Administration (NOAA) in particular, and inside by establishing an Earth Sciences and Applications Division within OSSA to augment the Earth science personnel and presence within NASA. In 1985, Edelson wrote an editorial in Science magazine. Dropping the “Global Habitability” name, he proclaimed the need for a new “Mission To Planet Earth.” While this planning and support-building was underway, events provided NASA an opportunity to demonstrate how it could lead in a new global environmental mission.

The issue was ozone depletion. It had risen and declined as an issue in the 1970s but in the mid-1980s had returned with a vengeance. In 1985, British scientists using ground-based studies discovered extraordinary and shocking ozone depletion over Antarctica. NASA quickly followed-up with satellite observations confirming what became known as the “ozone hole.”

The media, using NASA satellite images, conveyed an eerie and graphic display of a gigantic hole that seemed to grow like an organism over Antarctica. The images alarmed the public, as they were accompanied with reports of how skin cancer could be caused by ozone depletion if the hole spread to more populated places. Scientists,

13. Edelson, “Mission To Planet Earth.”
media, environmentalists and politicians sounded the alarm. Industry defended itself against over-hasty regulations, but was on the defensive.

NASA seized the initiative. It had the legislation from the 1970s that gave it legitimacy to take a “lead agency” role on the science side of this issue. It organized a scientific expedition to Antarctica. Enlisting NOAA, NSF, academic scientists from the United States and abroad, and even industry researchers, NASA and its allies sought to determine the cause of the hole. Robert Watson, an energetic OSSA manager, was the prime mover in the Antarctic expedition. He struck a close alliance with a key scientist-administrator of NOAA, Dan Albritton, and practiced what Albritton called “ecumenical” leadership. One Antarctic expedition was soon followed by another, more extensive one. It became increasingly clear to the scientists that the prime suspects behind the hole were common chemicals called chlorofluorocarbons, or CFCs, found in a host of everyday products. This growing consensus extended to industry scientists involved in the expedition and was endorsed by an independent group of scientists Watson set up to review the expeditions’ findings.

Watson and Albritton played dual roles—scientist-administrators of two agencies collaborating in an ad hoc program to determine causality in ozone depletion, and science advisors to the State Department and the EPA. These “policy agencies” were users, in real time, of information from the science agencies. There was again a push and pull on the part of providers and users. The technical information—what was known and what was not known—was conveyed to diplomats in the field. The diplomats were meeting under international political pressure to act, and did so in 1987, producing the pathbreaking Montreal Protocol, an agreement which set deadlines for replacing CFCs with less harmful chemicals. The Montreal Protocol was remarkable in calling for amendments as science produced more precise knowledge. Ozone depletion in many ways became the model for subsequent international environmental policy.

It was also seen as a potential model for NASA. NASA leaders contemplated ozone depletion as the first step in the broader global environmental initiative it had sought since 1982. The ozone experience, highly positive for NASA in a public relations sense, took place in a period when the Agency otherwise suffered severe criticism for the Challenger Space Shuttle disaster. That disaster, in 1986, had brought James Fletcher back to the Agency. While presiding over NASA’s return to flight, he also looked ahead to new missions. He asked Sally Ride, America’s first woman in space, to study possible initiatives beyond the space station, NASA’s existing flagship project, that would give long-term direction to the Agency. Her 1987 report listed four options, without giving any priority. The first she listed, however, was a Mission To Planet Earth. Calling the mission of “fundamental importance to humanity’s future,” Ride said NASA was “uniquely suited to lead the effort.” In the wake of the ozone experience, NASA was now in a far better position to make the case politically for a new mission than it had been in 1982.  

---

15. Lambright, “Entrepreneurship and Space Technology.”
Achieving Policy Adoption

Advocates of the new mission, largely in OSSA, began pushing harder for policy adoption of a new program. Drawing on the work of the Earth System Science Committee, which completed its studies in 1986, NASA set as the new program’s centerpiece an Earth Observation System (EOS). EOS would feature two 13-ton, bus-sized platforms launched by the Space Shuttle and linked with the Space Station Freedom. They would have multiple sensors, enough to permit comprehensive and simultaneous views of land, atmosphere, and sea interactions. The estimated cost of a system that delivered 15 years of observations was $30 billion. The full system would be launched by 2001. A series of specialized “precursory” missions in the 1990s would lead up to the main event, an operational two-platform EOS replete with an unprecedented data-handling and disbursing system. The EOS vision included potential additional systems contributed by other nations.

A program this big could only be justified if applied to a very big problem. The problem that had emerged over the 1980s in parallel with EOS planning was called “global change.” Global change included, but was not limited to, climate change. Climate change was a politically neutral way of referring to global warming. Global warming was controversial among scientists and even more so among politicians. Climate change was a much more complicated problem than ozone, both scientifically and politically. Climate change had even been connected with scientific opposition to the Reagan administration’s nuclear weapons policy. Scientists, led by space scientist Carl Sagan, warned against a “nuclear winter” if atomic weapons were ever used. Whether hot or cold, Earth’s climate was complex and many scientists felt it premature to forecast a dire future, for whatever reason, given existing understanding. Moreover, there was not an ozone hole to focus scientific work and trigger policy action. Instead, there was a slow accumulation of contentious scientific information. Although NASA’s lead role in investigating ozone depletion might be seen by the Agency to be a model for a Mission To Planet Earth, the transfer of the model to climate and global change would not be straightforward. NASA had no special legislation that gave it legitimacy to assert its claims, but at least one man within NASA was asserting his own views.

In 1988, James Hansen, director of NASA’s Institute for Space Studies, proclaimed before Congress that global warming was almost certainly a reality now. He declared to reporters afterward that it was time to “stop waffling and say that the evidence is pretty strong that the greenhouse effect is here.” His view was not popular with the Reagan White House. The Reagan administration established an interagency committee, whose dominant members were NASA, NOAA, and NSF, to get at the facts. From this committee, initially called Committee on Earth Sciences (CES),

---

came the proposal for a U.S. Global Change Research Program (USGCRP). When George H. W. Bush became president in 1989, CES had a report waiting for him and his science advisor, Alan Bromley. Bush said he wished to be “the environmental president” and, on the advice of Bromley, made global change his first “presidential priority” in science and technology. Such a designation slated global change for policy adoption and budget support. The USGCRP combined space and ground-based observations. The largest single item in the interagency effort would be EOS, but NASA was not a “lead” agency. Leadership was vested in the USGCRP interagency committee, whose name was broadened, along with its membership, to Committee on Earth and Environmental Sciences (CEES). In 1990, Bush officially adopted Mission To Planet Earth as a NASA priority. Congress provided endorsements and an initial appropriation to start EOS. The advocates of a greater NASA role in global environmental monitoring thereby achieved a victory after almost a decade of planning and strategizing. NASA was poised to use space technology in a grand effort to develop an “Earth System Science.” Such a science would pave the way for a “predictive capability” in global change that would guide policy makers, and thereby protect planet Earth.17

WOUNDED AT THE OUTSET

In theory, a new government program moves from adoption to implementation, at which point it has the opportunity to show its mettle before later undergoing evaluation and possible mid-course correction. Not so MTPE/EOS. NASA’s environmental initiative faced drastic reorientation almost as soon as it got underway, before implementation could commence in a serious way. There were five obstacles to stable growth it confronted in the years of George H. W. Bush. The first was a larger, more compelling national policy imperative concerning the overall federal budget. With the cold war waning and the federal budget deficit soaring, politicians increasingly wanted to cap spending on discretionary programs as much as possible to lower the deficit. This put all “big science” programs in danger, and EOS was clearly big science at a projected $30 billion. The Bush White House and Congress pressed NASA for redesign to lower costs.

OSSA’s associate administrator, Len Fisk, argued in 1991 for staying the course in plans and budget. Stating that a “comprehensive” approach was essential, he declared that Earth was “too complicated, and its workings too interrelated” for a piecemeal strategy. “It’s a big Earth,” he stated. “and there are big consequences for getting the wrong answers.”18 Unfortunately for EOS, there was a second problem: lack

---

17. Lambright, “Entrepreneurship and Space Technology.”
of cohesion in support on the part of the scientific-environmentalist constituency. NASA’s own Hansen, clearly alarmed about the global warming issue, said that the comprehensive approach of EOS would take too long to show results. While saying he supported EOS, he proposed a short-term, smaller-satellite strategy specifically geared to resolving the climate change debate. The Hansen view was shared by various environmentalists and their prime legislative spokesman, Senator Al Gore (D-Tennessee). Many environmentalists in fact regarded EOS as an administration delaying tactic—researching instead of responding to climate change with emissions controls. At a time when Fisk needed solid backing for EOS, there were fissures in his potential scientific and environmental constituency.

The third problem Fisk faced was that NASA’s flagship program, Space Station Freedom, was running into serious opposition in Congress. In her 1987 report, Ride had mentioned MTPE as one of four new initiatives that would build on the space station. However, EOS seemed now to be competing with the space station for funds. Both programs would cost billions. Congress told Bush and NASA: prioritize! When Congressional threats to terminate the space station forced Bush and NASA Administrator Richard Truly to choose, they made it clear that the space station was their priority. Congress in 1991 directed NASA to cap EOS expenditures at $11 billion through the year 2000. This was $6 billion less than NASA had projected during the 1990s for the two-platform design. Reorientation of the program became essential.

The fourth obstacle to the program adopted in 1990 came in April 1992, when Dan Goldin arrived as NASA Administrator. By this time, the two-platform design was giving way to a fleet of six satellites, carrying fewer instruments. Goldin removed Fisk and reorganized OSSA into three smaller units. MTPE/EOS survived, but Goldin demanded it adhere to his philosophy of faster, better, cheaper (FBC). He called the original EOS design a “Battlestar Galactica,” and even the six-satellite fleet failed his criteria.

The fifth obstacle to implementing the original vision was the end of the relative political bipartisanship that had made adoption of MTPE/EOS possible in the first place. In the view of some conservative Republican lawmakers, NASA became politicized in the early 1990s. Ironically, NASA gave ammunition to its critics. As it shifted emphasis from ozone depletion to global climate change, it continued its ozone work, using the first satellite deployed under the MTPE rubric, the Upper Atmosphere Research Satellite (UARS). The focus of NASA’s ozone research moved from the South Pole to the Arctic. NASA researchers in early 1992 detected an Arctic ozone hole opening up and publicly announced that fact with a sense of alarm.

Environmentalists, the media, and various legislators demanded action. Senator Gore, whose book, *Earth in the Balance*, came out in 1992, pointed out the danger of an Arctic ozone hole spreading over populated territory in the North. Critics of Bush said that there would soon be an ozone hole over Bush’s head in his summer home in Kennebunkport, Maine. Bush did in fact act, using powers he had under domestic legislation related to the Montreal Protocol. He ordered a speed-up in the phasing out of ozone-depleting chemicals. There was thus again a swift progress from science to policy. The only problem this time was that NASA subsequently admitted that it had sounded the alarm prematurely and that there was no Arctic ozone hole. Nor, said a chastened NASA spokesman, was there a hole over Kennebunkport.  

The consequence was that conservative lawmakers and media seized the moment to criticize NASA’s credibility and link the space agency to the environmentalists’ agenda on global warming. As Bush left office, NASA’s environmental mission was flayed by critics as politicized, and opposition in Congress loomed. Thus, in the course of just four years—one presidential administration—NASA’s environmental mission went seemingly from a high priority of NASA and the nation, with bipartisan support, to an embattled program struggling to survive, technically and politically.

**More Turbulence Under Clinton**

The inauguration of Bill Clinton as president, and especially Al Gore as his vice president, in 1993 guaranteed that NASA would continue to have an environmental role. The issue remained one of content and scale. Clinton retained Goldin as NASA Administrator, and NASA’s Robert Watson moved up to the White House Office of Science and Technology to a new post of associate director of the Office of Science and Technology Policy (OSTP) for Environment. 

The problem for MTPE/EOS was that Clinton, not Gore, was president. Also, both men had many other priorities and were far more interested in environmental action—including CO2 emissions reduction—than a long-term research program like EOS. Moreover, the larger enterprise of which EOS was the centerpiece, USGCRP, continued but lost momentum as a federal coordinating vehicle. The interagency committee that led USGCRP (and to some extent MTPE/EOS) found itself engaged in turf battles with the OSTP Environmental office. “Who was in charge of what” became an issue that caused confusion in global change policy generally.  

Most importantly, Clinton made deficit reduction and economic growth his top priority and looked to NASA for budget savings. There was at first no guarantee that NASA’s major program, Space Station *Freedom*, would survive the transition.

---

to the Clinton White House and the new Congress. Following Clinton’s decision to reduce the space station in scale and then his decision to merge Space Station Freedom with Russia’s Mir-2 space station effort, the NASA flagship project was secured within the NASA budget. The president and Congress agreed to stabilize the budget of the newly rechristened International Space Station (ISS) in succeeding years. However, the overall NASA budget would hold steady or even decrease, thus putting strain on other programs.

Goldin applied his faster, better, cheaper formula to space science and MTPE, but his heart was clearly more with missions beyond Earth, especially Mars, than Mission To Planet Earth. He cut the MTPE/EOS budget further and brought Charles Kennell, an astrophysicist from UCLA, aboard to head MTPE. Shelby Tilford, architect of the EOS program under Fisk, departed, complaining that faster, better, cheaper was not better in EOS’s case. The budget for EOS was now down to $7.25 billion for the period from 1993 to 2000. Kennell’s job was to reorient EOS further and adapt MTPE generally to Goldin and administration priorities. Adaptation included Landsat’s return. Landsat, a 1970s NASA initiative, had spun off in the 1980s to NOAA in what proved a fruitless effort to privatize the program. It now came back to NASA to become part of an effort to bring space remote sensing applications “down to Earth.” The aim was to apply space remote sensing to agriculture, city planning, fisheries, and other practical concerns. The new emphasis won friends for the program in Congress and the states. The flagship MTPE program, EOS, continued in development but its ambition was lowered in accord with the budget.

Although MTPE won friends because of its new “down to Earth” approach, EOS continued to be a target of critics. Because of its association with global change and especially global warming, EOS continued to be controversial. When the Republicans gained control of Congress in 1995, they sought substantial cuts in EOS. Rep. Dana Rohrabacher (R-California), chair of the House Science Committee’s Energy and Environmental Subcommittee, derided EOS as concerned with “scientific nonsense.” Global warming, he charged, was at best “unproven and at worst . . . liberal claptrap.” Goldin strongly defended MTPE/EOS and, in the end, the effort to make draconian cuts failed.\textsuperscript{24} The budget projection did go down, however, to $6.8 billion, along with NASA’s budget generally.\textsuperscript{25} Defenders of EOS commented sardonically that it was “restructured,” “rescoped,” “rebaselined,” and “reshaped.” In the end, it stabilized around the development of three intermediate-sized, multi-sensor satellites, one oriented to land, another to water, and the third to the atmosphere.

MTPE/EOS in the Second Clinton Administration

There was relative stability for MTPE/EOS in Clinton’s second term. To be sure, every year was a budget struggle. However, the precursor and applications missions showed results and the three EOS satellites made progress in development. Some of the partisan heat surrounding the program cooled, aided perhaps by NASA’s changing the name of MTPE in 1998 to the more innocuous “Earth Sciences.” The aim was to emphasize it as a policy-relevant, not policy-driven, science program—a subtle shift. Gore did not help NASA’s effort to convey a neutral-science approach, however, when he proposed a new environmental satellite, called Triana, largely as an educational/inspirational tool. Detractors called it “Goresat” and Congress postponed its introduction, thereby taking some of the political heat off NASA.26

Meanwhile, positive results for the environment did flow from NASA precursor (i.e., pre-EOS) missions. The Agency’s work in ozone was continuing to bear fruit. The UARS satellite helped NASA monitor ozone depletion and thus global compliance with the Montreal Protocol. Although it would take years for the ozone depletion problem to be fully alleviated, there was evidence that the depletion situation was beginning to improve.

Other important results in precursor missions lay with El Niño. Working with France, NASA developed a specialized satellite, called Topex-Poseidon, for measuring sea-surface temperatures. In March 1997, Topex-Poseidon detected a significant rise in sea level that spread across the Pacific toward the South American coast. In April, it found a rise in sea-level temperatures off the coast of Ecuador and Peru and monitored its spread north and south. This early discovery of a developing El Niño indicated that space technology, linked with other technologies of communication, could provide early warnings for natural disasters associated with the El Niño phenomenon.27 Similarly, in 1998, NASA used the Tropical Rainfall Measuring Mission (TRMM) satellite to model more precisely the formation of hurricanes and other storms off the coast of Florida. Topex-Poseidon and TRMM again pointed up the practical value of environmental satellites. NASA’s work in these “near-term” disasters was generally applauded. It still ran into controversy when it came to global warming, however. This was because it could not avoid what was happening in its political setting, where the controversy over the issue intensified.

In late 1997, Vice President Gore defied Congressional sentiment when he went to Kyoto, Japan, and agreed to a protocol with other nations to cut back greenhouse gas emissions by a specific amount over a designated span of time. Clinton said he agreed with Gore but that he would not submit the Kyoto Protocol to the Senate for confirmation. He would instead emphasize voluntary measures to reduce emissions to Kyoto standards. The political consensus for binding emissions reduction and thus the regulation of the energy and automobile industries was not present, in Clinton’s view. The political debate over Kyoto spilled over to make the setting for research on climate change more conflictual. 28

In 1999, NASA launched the first of its climate-related EOS satellites, Terra. This satellite emphasized land masses but also had sensors relevant to other aspects of the physical environment. At $1.3 billion, Terra was intermediate in scale. Although far from the original concept, it was bigger than the faster, better, cheaper model Goldin had initially promoted. The remaining two satellites in the three-satellite series were scheduled to go up in the first term of Clinton’s successor.

**Environment at NASA Under George W. Bush**

When George W. Bush became president in January 2001, the major policy question for the new administration involving NASA and the environment was: What would be NASA’s role in environmental research after EOS? The answer has come slowly, tortuously, and is still emerging.

In March, Bush withdrew the United States from agreements under Kyoto. The negative reaction to that decision in the United States and Europe caused him to subsequently announce he would support research on climate change and take policy action if it proved necessary. The USGCRP was maintained under a new label, Climate Change Research Initiative, with the assistant secretary of commerce in charge of the interagency effort. For a year, NASA’s Earth Science program was essentially on hold while the administration determined what it would do. Meanwhile, at the beginning of January 2002, Sean O’Keefe came aboard as new NASA Administrator. O’Keefe’s priority was the ISS cost overrun, not Earth Sciences, but he provided support for EOS to complete what had begun under Goldin. The first EOS satellite was performing well, and the second, Aqua (costing $1 billion), was launched May 4. As its name implied, Aqua’s mission was to study the global water cycle, including precipitation and evaporation. 29 O’Keefe also symbolized NASA’s environmental concern by including in its mission statement the phrase “To understand and protect our home planet.”

---

On 1 February 2003 the Columbia Space Shuttle disintegrated, killing all astronauts aboard. Once again, momentum for NASA’s future, Earth Sciences included, was interrupted. That there would be some kind of future for Earth Sciences seemed clear. In the summer 2003, the State Department held an International Earth Observations Summit. The United States pledged to provide leadership in climate change research through an international “system of systems” in which satellite capabilities of many nations would be coordinated and linked. Following the conference, NASA announced it would develop on an accelerated pace a new, post-EOS, climate change-oriented satellite called Glory.\footnote{Brian Berger, “Reversing Course,” Space News (25 July 2005), p. 10.}

On 14 January 2004, President Bush announced his Vision for Space Exploration (VSE) initiative, “To the Moon, Mars, and Beyond.” In line with the new priority, O’Keefe reorganized the Agency, creating an Exploration Systems Division and merging NASA’s separate Earth Science and Space Science programs into a single organization, the Science Mission Directorate. Proponents of Earth Science viewed the reorganization as a downgrading in priority. Advocates of reorganization argued that the moving of Earth and Space Science together promoted synergy and enhanced learning about planetary change in general from work on Earth, Mars, and other planets. They gave a comparative planetology perspective, one historically always present as part of NASA’s environmental mission but usually as a background element. Now it was moved to the foreground to emphasize mutual learning from missions to and from Earth.

In July, NASA launched Aura, the third and final leg of EOS. Another billion-dollar satellite, Aura would make comprehensive measurements of the atmosphere and take over for the aging UARS in monitoring ozone trends.\footnote{Tariq Malik, “Last EOS Satellite to Study Air Quality at Earth’s Surface,” Space News (14 June 2004), p. 8.} The completion of EOS after so many years was a matter of relief for some Earth Science observers, but frustrating for others. Valuable though they would be, the EOS satellites were far short of the program creators’ vision: large dual platforms providing comprehensive and simultaneous air, land, and sea interactive images over a 15-year time frame. There were many gaps in knowledge to be filled.

The more pressing problem continued to be: What next for Earth Sciences? Especially: What next in an era when Moon–Mars would increasingly shape all priorities for NASA? That is, the closer a program was to VSE, the more relevant it could be seen to be to NASA’s future. The further away, the less relevant. There was a great deal of concern among scientists and administrators involved with NASA’s environmental mission that, when push came to shove, they would suffer. Indeed, budget projections seemed to indicate that fact, as did a decision to cancel the Glory climate satellite. Moreover, there were rumors that the administration was considering moving much of NASA’s Earth observation work to NOAA.
The future remained murky when O’Keefe departed and Michael Griffin came aboard as NASA’s leader in April 2005. Griffin reversed a number of O’Keefe’s decisions, including the Glory termination. Earth Science had friends in Congress, especially Sherwood Boehlert (R-NY), chair of the House Science Committee. However, Griffin had to deal with the reality of increased shuttle repair costs and a relatively static overall NASA budget. If VSE were to move forward, money would have to come from lower-priority programs, including Earth Sciences. At the same time, the cross-pressured Griffin found himself dealing with a highly public dispute involving NASA’s outspoken James Hansen. The NASA scientist complained to the media that administration appointees in NASA’s public affairs office were censoring his statements about global warming. Griffin declared that NASA scientists could comment freely about science, and even its implications, but they should make clear that they spoke for themselves, not NASA, when they crossed the line into policy. A NASA public affairs official who had allegedly censored Hansen was fired when it was revealed he had lied about his educational credentials.

In 2006 Griffin presented a budget that delayed various post-EOS missions but reinstated Glory. EOS orbited and provided considerable information, but there was worry about whether there was enough money to analyze the information properly. There were also various older specialized satellites, including Landsat, which needed replacement in some way. NASA was a junior partner in a NOAA-Department of Defense operationally-oriented system called the National Polar Orbiting Operational Environmental Satellite System (NPOESS). For a while, the Bush administration seemed intent on linking NASA’s post-EOS climate science future to NPOESS, but when NPOESS ran into budget problems of its own, connecting NASA’s climate role to NPOESS lost a great deal of its rationale.

What NASA needed was an overarching strategy for its future in Earth Science, one like the one it developed in the 1980s prior to the birth of MTPE and EOS. To help provide advice, the National Research Council undertook an Earth Science decadal survey on priorities in the next 10 years. To be completed by November 2006, the survey was intended to help Griffin determine what made sense for the Earth Sciences program. Griffin, in turn, would require major decisions from the White House and Congress to set NASA on a course fruitful both for science and climate policy.

34. Berger, “Reversing Course.”
Without question, the Earth Science program was at a crossroad. NASA’s environmental role was not explicitly mentioned in the overarching NASA mission statement of 2006. The phrase O’Keefe had used in his mission statement—“To understand and protect our home planet”—was gone. The new Griffin mission statement read “To pioneer the future in space exploration, scientific discovery, and aeronautics research.” Whether the omission was symbolic or substantive remained to be seen. The basic problem NASA Administrator Griffin has faced is that he has too many programs on NASA’s plate and not enough money for all.

**Conclusion**

How did NASA evolve an environmental mission? The answer is that it did so gradually and somewhat tortuously, with ups and downs along the way. What did it do with that mission? It did a great deal that was positive in a host of ways, but with special significance in regard to ozone depletion and the Montreal Protocol. What has this meant for society? It has meant benefits in knowledge with spillover into policy. What has the environmental mission meant for NASA? It has meant enmeshment in a political context that has helped it survive and grow at some points in history and made it extremely controversial at other times.

Taking the long view of history, NASA has had an enormous impact on environmental policy since its founding in 1958. The weather satellite and its successors, developed by NASA and transferred to operational use, have saved lives and money through early warnings of hurricanes and improved weather forecasting. The first pictures of Earth from the Apollo program crystallized the vulnerability and beauty of Earth and were used by environmentalists to mobilize support for the first Earth Day in 1970. As the environmental movement gathered momentum, NASA in the 1970s aligned itself with the new imperative and extended its weather satellite effort to land- and sea-oriented images. This activity took place as NASA’s planetary program stimulated a comparative planetology consciousness in which Earth seemed increasingly unique as a home to life. The Gaia Hypothesis, which emerged from comparative planetology, stressed thinking about Earth as a living system of interacting and interdependent parts.

In 1972, with Landsat, NASA initiated a long series of Earth monitoring satellites. In doing so, it became more and more, as NASA administrator Fletcher said, “an environmental agency.” Becoming “an environmental agency,” through the science it provided, immersed NASA in the controversies and political emotions surrounding the environmental question. Sometimes the political winds were favorable to NASA; at other times they were not so. In the 1980s NASA, armed with

---

legislative authority gained in the 1970s, played a lead role within the government in responding to the ozone depletion threat. It was the ozone crisis that provided a proactive model for NASA as an environmental agency, one that could conduct and transfer policy-relevant science. Advocates of a larger global environmental mission sought to build on the ozone success to position NASA for an expanded role. After Challenger, in 1987 Sally Ride listed Mission To Planet Earth as first among new initiatives that could galvanize a shaken agency and make it more relevant to American society and the world’s needs.

Such a mission seemed ripe indeed in the wake of the Montreal Protocol as the new concern about climate change rose on the nation’s agenda, propelled in part as NASA’s James Hansen. President George H. W. Bush and Congress in 1990 provided authority and initial funding for MTPE and its centerpiece, EOS. However, in the 1990s, MTPE ran into a budgetary crunch and competition with other NASA programs—human spaceflight and space science—and was never funded as its founders expected. EOS was downsized and split up, subject not only to budget constraints but also pressures to conform to Goldin’s faster, better, cheaper doctrine. What finally was launched as EOS in 1999, 2002, and 2004 was a much circumscribed version of what its architects had planned in the late 1980s. The system could not realize the promise of a 15-year comprehensive data set from the simultaneous monitoring of land, sea, and atmosphere interaction. A new Earth System Science got started but did not get as far as expected. The “predictive capability” remained to be developed for global change.

With ozone depletion, NASA had legitimacy to lead and a crisis context in which there was science push and policy pull. With climate change, however, NASA had no special mandate to lead and the science push has come gradually in a societal context where the perception of crisis is lacking. Rather than policy pull, there has been policy discord and even “push back.”

A strategy for the post-EOS era has yet to be fully charted and adopted, much less implemented. Agreement on next steps has to be forged. It is easy today for advocates of global environmental satellites to see a glass half empty. However, a more positive, glass half-full view surely would say that it is remarkable how much a space agency has done in directing attention to Earth. NASA is the space research and development arm of the federal government when it comes to global environment. In addition to EOS, there have been numerous specialized satellites that have monitored ice melting, El Niño, storms, and others ills. Ozone provides a genuine success story in science and public policy. There was science-push and policy-pull. Climate change is not a success story yet. If one were giving grades, NASA would get an “A” for ozone depletion and “Incomplete” for global climate change. Having said that, the problem of climate change is more complex than ozone for many reasons, and there has been consensus-building progress, at least on the science side. There is a limit to what NASA (and science generally) can do in eliciting policy response, however.
The dilemma NASA now faces in designing a post-EOS future is shared with other agencies associated with the global change initiative of the early 1990s. This interagency initiative never was fully implemented, coordinated, or led. There is a need to re-energize the vision many of the early advocates of EOS and USGCRP had—a strong Earth system science and a capacity to predict global change (especially climate change)—that can be put to policy use. Achieving such a vision requires a planetary perspective and that is NASA’s distinctive environmental competence. It is based on NASA’s mission to the home planet and the comparative approach derived from its work beyond Earth. That perspective needs renewal and advocacy for a twenty-first century setting. That setting almost surely will be influenced, perhaps dramatically, by events involving climate change. Remaking NASA’s environmental mission, with resources to match, and connecting that role to other agencies and nations is a challenge. It is less a problem in science and technology, however, and much more a challenge of political will.
Chapter 17

NAVSTAR, the Global Positioning System: A Sampling of Its Military, Civil, and Commercial Impact

Rick W. Sturdevant

Historical Background

The NAVSTAR1 Global Positioning System (GPS), the first satellite navigation system that enabled users to determine precisely their location in three dimensions and time within billionths of a second, grew from a concept into a fully operational system in slightly more than two decades. This is not to suggest, however, that selling the idea was easy. As early as 1969–1970, Aerospace Corporation president and GPS pioneer Ivan Getting had suggested to Lee DuBridge, President Richard Nixon’s science advisor, that a presidential commission be created to review how satellite navigation ought to proceed, because there were so many potential users. After thinking about it for several weeks, DuBridge concluded that execution of Getting’s proposal would be too difficult. He told Getting, “There are too many people, too many bureaucracies, too much politics, and too many agencies involved. Why don’t you just have the Air Force develop it the way we always did?”2

By 1972, both the U.S. Air Force (USAF) and the U.S. Navy had been studying for several years the possibility of improved satellite-based radio navigation. Three earlier space-based navigation systems or programs contributed to GPS: The Johns Hopkins University Applied Physics Laboratory (APL) Transit, otherwise known as the Naval Navigation Satellite System; the Naval Research Laboratory’s Timation satellite program, led by Roger Easton; and USAF Project 621B. Colonel Bradford

---

1. Over time, some people identified “NAVSTAR” as an acronym derived from either “Navigation Signal Timing and Ranging” or “Navigation Satellite Timing and Ranging.” Apparently, TRW had once advocated a navigational system for which NAVSTAR was an acronym (NAVigation System Timing And Ranging). Bradford W. Parkinson, “GPS Eyewitness: The Early Years,” GPS World 5 (9 September 1994): pp. 32–45, explained that his team at the Joint Program Office never considered “NAVSTAR” an acronym but “simply a nice-sounding name.”

Parkinson, USAF director of the newly formed multi-service Joint Program Office (JPO) for GPS, assembled about a dozen members of the JPO over Labor Day weekend in 1973 and directed them to synthesize the design for a new satellite navigation system by drawing the best ideas and technology from everything then available.³

From that point, GPS developed at a reasonably steady pace. By June 1974, the JPO had selected Rockwell International as the satellite contractor. The JPO oversaw deployment of the initial control segment at the Army’s Yuma Proving Ground in Arizona, followed by the launch of the first operational prototype in February 1978. Eleven years later, in February 1989, the USAF launched the first fully operational Block 2 version. Although a complete constellation of 24 Block 2 satellites existed in December 1993, GPS did not officially achieve full operational status until April 1995. It had cost $10–$12 billion to field the system, and the USAF estimated the cost annually of sustaining minimal GPS services at $400 million.⁴

The main reasons for GPS development were the need to deliver weapons precisely on target and to reverse the proliferation of navigation systems in the U.S. military. From the beginning, however, the Department of Defense (DOD) recognized the usefulness of GPS to the worldwide civilian community. To withhold full accuracy from enemies but provide GPS service to civilian users, the USAF designed the system with a protective feature called “selective availability” (SA) that, when used, gave the U.S. military and its allies significantly more precise satellite signals than what other users received. After Korean Airline Flight 007 went astray in September 1983 and Soviet fighters shot it down, President Ronald Reagan reassured the world that the coarser signal would remain continually and universally available at no cost once GPS became fully operational. As GPS approached that status in the early 1990s, civilian and commercial users, who already had 10 times as many GPS receivers as the military, mounted an increasingly vocal campaign for unrestricted access to the more precise satellite signals. Many GPS equipment manufacturers, anticipating a multitude of applications, had begun forming strategic alliances with outside companies in such fields as communications, Geographic Information Systems (GIS), computing, and transportation. Finally, in May 2000, President William Clinton acknowledged the global utility of GPS and directed immediate discontinuation of SA, thereby giving millions of nonmilitary users access to the more precise GPS signals.⁵

---

With increasing demand for accuracy beyond what GPS alone yielded, users found ways to augment it. For small areas, those included pseudolites (ground-based transmitters that could be configured to emit GPS-like signals) and differential GPS (DGPS), which required a high-quality GPS "reference receiver" at a known, surveyed location. Wide Area DGPS (WADGPS), involving reference receivers at multiple monitor stations and a master-control hub, would achieve similar results over a broader region. An example of WADGPS was the Wide Area Augmentation System (WAAS), which the Federal Aviation Administration (FAA) believed would eventually provide the integrity, reliability, time availability, and accuracy to permit pilots and air traffic controllers to rely confidently and safely on GPS as their primary navigation system. By 2006, continuously operating reference stations (CORS), coordinated across the United States by the National Geodetic Survey, enhanced GPS services to millions of users. Meanwhile, other countries and geographic regions had begun developing their own GPS augmentation systems: the European Geostationary Navigation Overlay System (EGNOS); India’s GPS and Geostationary Augmentation Network (GAGAN); Australia’s Ground-based Regional Augmentation System (GRAS); and Japan’s Multi-transport Satellite Augmentation System (MSAS). In addition, Russia operated its own Global Navigation Satellite System (GLONASS); China experimented with its Beidou navigation satellites; and Europe pressed hard toward launching the Galileo satellite navigation system. Whether all those capabilities could be melded into a fully integrated Global Navigation Satellite System (GNSS) remained a question without an immediate answer, but the military, civil, and commercial utility of GPS was unquestionable. Since a full accounting of the GPS’s societal impact would require hundreds of pages, what follows is merely suggestive.

Military Applications

The first weapon in the U.S. arsenal to become operational using GPS navigation was the Conventional Air-Launched Cruise Missile (CALCM) or AGM-86C. Its development began in June 1986 when Boeing Company received a 12-month contract for rapid conversion of existing ALCMs, the inaccuracy of which had resulted in accidentally bombing the French Embassy during Operation Eldorado Canyon, a night attack against Libya two months earlier. A loosely coupled integration of GPS capabilities with the missile’s existing inertial navigation system (INS) permitted Boeing to deliver the first CALCMs to the U.S. Air Force in June 1987. During the initial hours of the air campaign for Operation Desert Storm in January 1991, seven B-52G bombers flying from Barksdale Air Force Base, Louisiana, delivered a total of 35 CALCMs against eight high-value targets in Iraq and achieved 85 percent to 91 percent success, including several exact hits.9

In the 1990s, the U.S. military fielded a host of air-dropped munitions that used GPS to one degree or another. Foremost among them, the Joint Direct Attack Munition (JDAM) turned fundamentally “dumb” bombs into high-precision ordnance capable of destroying multiple targets in a single sortie any time of day or night, in any kind of weather, no matter how adverse. During Operation Allied Force, the NATO air campaign against Serbia in 1999, U.S. B-2 Spirit bombers dropped more than 500 relatively inexpensive JDAMs with such great success that U.S. military strategists foresaw the possibility of unguided bombs completely disappearing from the arsenal. Other GPS-aided U.S. aerial weapons that debuted in the 1990s included the AGM-154 Joint Stand-Off Weapon (JSOW), the AGM-130 air-to-surface missile, the BGM-109 Tomahawk cruise missile, and the SLAM-ER (Stand-Off Land Attack Missile—Enhanced Response).10

A suite of technologies known as Advanced Spinning-Vehicle Navigation (ASVN) permitted GPS/INS guidance in smaller and smaller munitions. By 2001, the U.S. Army planned to use it in artillery shells; the U.S. Navy had similar plans for rocket-assisted projectiles fired from its deck guns. The Army’s howitzer-fired, 155-mm XM982 Excalibur round underwent a demonstration at Yuma Proving Ground, Arizona, on 15 September 2005 in which its accuracy was better than 33 ft (10 m) at a distance of 9 mi (15 km). Excalibur tests continued into February 2007, with operational fielding scheduled for later that year. A Navy contract with Raytheon Missile Systems, primary designer of the Army’s Excalibur, called for development of the 5-in (13-cm) MK-171 Extended-Range Guided Munition (ERGM). Although achieving satisfactory ERGM performance proved harder than

for Excalibur and delayed its operational deployment, flight demonstrations at White Sands Missile Range, New Mexico, on 16 February 2005 proved the ERGM could achieve great accuracy at a distance of more than 40 nautical miles. In both cases, these new projectiles offered greater lethality and lower collateral damage, with increased range and a considerably reduced logistical burden for deployed forces.11

In early 2003, the public became aware of GPS guidance for precision airdrops. The U.S. Army Operational Test Command employed GPS in two different instrument packages—one to verify the optimal parachute rigging for heavy cargo pallets, and the other to evaluate new troop-parachute designs. Within months, the U.S. military operationally tested Onyx, an autonomously guided parachute system developed by Atair Aerospace, for delivering payloads ranging from 75 to 2,200 lbs (34 to 998 kg) within 246 ft (75 m) circular error probable from altitudes up the 35,000 ft (10,668 m) in darkness and other extreme conditions. On 9 August 2004, U.S. Marines near Camp Korean Village, Iraq, witnessed the first operational use of a GPS-assisted Sherpa parafloat cargo delivery system, a key component of the Joint Precision Airdrop System (JPADS) technology demonstration program, in a combat zone. Two years later, the first joint Air Force-Army operational drop using JPADS in Southwest Asia supplied ammunition and water to troops in Afghanistan. Meanwhile, design and testing of GPS-equipped navigation units for paratroopers proceeded. In 2005, the French Military Agency (DGA) and Army Special Forces in Singapore were using more than 200 GPS-assisted Operational Paratroopers Navigation System (OPANAS)

units produced by SSK Industries, and North Atlantic Treaty Organization (NATO) countries were testing OPANAS for high-altitude, high-opening (HAHO) jumps. These new capabilities ensured more accurate landings for both cargo and troops in all kinds of conditions and, by permitting releases from altitudes above 25,000 ft (7,620 m), protected aircraft and personnel from hostile forces armed with inexpensive surface-to-air missiles. Onyx autonomously guided parachute system using GPS navigation.

After 2000, a rapidly expanding family of autonomous or remotely controlled robotic military systems relied on GPS navigation to perform a wide variety of tasks on land, at sea, underwater, and in the air or outer space. Unpiloted aerial vehicles (UAVs) equipped with GPS, which had been under development since the 1980s, flew reconnaissance and surveillance missions over Bosnia and Kosovo during the late 1990s and, thereafter, proliferated among military organizations worldwide. In 2001–2002, Predator drones carrying AGM-114 Hellfire missiles attacked Taliban and Al Qaeda forces in Afghanistan. On 25 January 2002, a GPS-Aided Inertial Navigation System (GAINS) on the third stage of an SM-3 interceptor launched from a U.S. Navy Aegis cruiser helped successfully demonstrate the exo-

atmospheric interception of an incoming target missile.14 During Operation Iraqi Freedom in 2003, the U.S. Navy ordered the first wartime deployment of the GPS-equipped, Remote Environmental Monitoring Units (REMUS) autonomous underwater vehicle (AUV) to locate suspected mines in the port of Umm Qasr.15 By November 2004, the DOD had contracted with Applied Perception, Inc. (API) to build two interrelated, GPS-enabled robotic prototypes—a 3,500-lb (1,588-kg) Robotic Evacuation Vehicle (REV) and a 600-lb (272-kg) Robotic Extraction Vehicle (REX)—for the safe recovery and transport of wounded soldiers from the battlefield to a nearby field hospital. Clearly, such vehicles could have numerous other military and nonmilitary applications ranging from logistical supply, ordnance disposal, surveillance, and assault to fire fighting, crowd control, soil sampling, pest abatement, and exploration of hazardous environments.16

Perhaps the most pervasive U.S. military application of GPS by 2006 involved the tracking and coordination of various battle elements in real time using the GPS-enabled Force XXI Battle Command, Brigade—and-Below (FBCB2) satellite-based tracking system and its Blue Force Tracking (BFT) variant. American soldiers had suffered roughly a quarter-million casualties in the twentieth century due to so-called friendly fire, primarily because of the difficulty during intense conflict of discriminating quickly between friend and foe. As early as springtime of 1987, engineers and scouts from the U.S. Army’s 4th Infantry Division used two 17.5-lb (8-kg) GPS manpacks during exercises in the Pinón Canyon training area of southern Colorado to maneuver through “enemy” lines in snow, rain, fog, and darkness to accomplish their objective. Four years later in Operation Desert Storm, with only 16 satellites in the constellation, GPS aided positioning and maneuvering of large troop formations, plus precision bombing, artillery fire support, and special operations in relatively featureless desert terrain. Coalition forces relying primarily on more than 12,000 personal receivers, each costing about $3,500, prevented countless casualties by reducing the so-called fog of battle.17

A decade after Desert Storm, U.S. forces conducting war games in California and Florida located and tracked troops, aircraft, and assorted equipment in real time using an Inexpensive Range Instrumentation System (IRIS). That experimentation demonstrated that low-cost, commercial off-the-shelf hardware could be used to coordinate ground and air activities, thereby enhancing the safety of friendly forces. By 2005, U.S. and allied forces in Kosovo, Afghanistan, and Iraq relied on more than 8,000 GPS-enabled FBCB2 units and another 2,000 FBCB2-BFT units to track their own positions, neighboring friendly forces, and spotted enemy forces along with the location of bridges, mine fields, and other potentially dangerous geo-points. In 2006, Globecomm Systems won a $7.8 million contract to provide NATO forces with a similar BFT capability. The enhanced situational awareness provided by FBCB2 and its BFT variant also allowed battlefield commanders to plan and coordinate maneuvers—offensive and defensive—with unprecedented precision.  

Navigation

The most rapidly expanding area of GPS use for civil, commercial, and personal purposes was probably location-based services (LBS)—positioning and navigation. Land-based users include automobile drivers, railroads, fleet managers of trucks, delivery vehicles, and public transportation; emergency responders such as fire, ambulance, and police; and recreational activities such as hiking, hunting, skiing, biking, and golfing. According to Alan A. Varghese from ABI Research in Oyster Bay, New York, shipments of recreational GPS devices alone rose from 3.2 million in 2002 to 5 million in 2003, with a predicted annual growth of 31 percent until 2009. Sea-based applications ranged from recreational sailing, fishing, and managing shipping fleets, to assisted steering, risk assessment, and hazard warning. Pilots of all varieties—airplane, helicopter, hot-air balloon—relied increasingly on GPS for monitoring their flight path, for collision avoidance, and for landing. Search-and-rescue personnel on land, at sea, and in the air all came to view GPS as indispensable. Ultimately, scientists and engineers experimented with using GPS for launch and on-orbit operation of spacecraft.

When GPS receiver technology and cellular phones started to become more affordable during the mid-1990s, industry analysts and entrepreneurs perceived LBS as an emerging multibillion-dollar market. By 2002, however, only two automotive companies—General Motors (OnStar) and Mercedes (TeleAid)—offered consumers telematic LBS; such factors as cost, technological drawbacks of early-generation systems, and privacy concerns had led to slower than expected market growth. Nonetheless, an April 2002 nationwide survey of 20,000 U.S. households revealed strong consumer interest in using GPS for security-related purposes, especially for stolen vehicle tracking, with more moderate interest in services such as real-time traffic alerts, navigation assistance, and monitoring family vehicles. By 2006, North American sales of GPS-equipped navigation systems built into many different makes of automobiles, in portable devices, and in cell phones totaled 4.5 million units, with an increase of nearly 50 percent anticipated for 2007. Demand for up-to-date digital maps, derived in large part using GPS, of 7.3 million miles of North American highways caused the revenues of Tele Atlas and Navteq Corporation, the two principal competitors, to grow by 57 percent and 26 percent, respectively, in 2005. Meanwhile, after a decade of work, developers were ready to begin marketing in the United States and Canada an in-vehicle navigation system (IVNS) that promised to save private motorists billions (in terms of gallons, hours, and dollars) by integrating real-time data on traffic incidents, construction, and traffic flow to suggest alternate routes.

Use of GPS-aided technology for management of vehicle fleets has saved governments and businesses hundreds of millions of dollars by enabling more efficient planning of routes, monitoring misuse by employees, or locating stolen vehicles. The proliferation of organizations and conferences promoting development of automatic vehicle location (AVL) systems and intelligent vehicle/highway systems (IVHS) began in the late 1980s and fostered a veritable parade of specific projects in the early 1990s. By 1993, cities including Denver, Colorado, and Dallas, Texas, had begun installing GPS-based AVL systems in their buses and other city vehicles to keep riders informed of projected arrival times, to assist mobility-impaired riders, and to expedite response time in emergency situations. Meanwhile, Netherlands-based

---

Büchner Transport, which owned 50 trucks and specialized in delivery of house plants, fruits, and vegetables under controlled temperatures throughout Europe, had experimented with a GPS-assisted AVL system in two of its trucks from December 1991 to June 1992 and decided, despite the high price of the hardware, to begin equipping its entire fleet over the next five years.23 During 1988–2004, San Diego-based Qualcomm, the largest AVL supplier worldwide, installed its position-reporting system on more than 500,000 commercial vehicles belonging to more than 1,500 trucking firms. By autumn of 2004, the Defense Transportation Tracking System used GPS-derived location reports to monitor annually more than 47,000 arms, ammunition, and explosives shipments by commercial motor carriers in the continental United States.24

Emergency responders found GPS capabilities invaluable. In January–May 1992, Amoco tested a GPS-aided response system in its large Crossfield natural gas field north of Calgary, Alberta, and concluded that it offered noteworthy cost and safety improvements over earlier systems by “providing nearly immediate identification of an alarm site and the nearest field personnel, as well as detailed maps that show the best route to the scene of an alarm.”25 The San Francisco Bay Area’s Freeway Service Patrol (FSP), a special team of approximately 40 tow-truck drivers who patrolled the most congested freeways during peak commute hours, began using a GPS-supported AVL system in August 1993 to assist stranded motorists. On average, FSP trucks arrived at the scene of a breakdown within seven minutes, almost six times faster than regular tow services.26 Also, in 1993, Doug Baker, founder and president of LaSalle Ambulance Service of Buffalo, New York, adopted a GPS-equipped tracking and dispatch system for his fleet of 42 vehicles, two aero-medical helicopters, and one fixed-wing aircraft to ensure speedier response times and, consequently, save more lives.27

Recovery of stolen vehicles became much more likely with GPS. Founded in 1998 by Pakistani crime fighter and businessman Jameel Yusuf, Trakker Pvt. Limited used GPS technology to track and recover more than 1,000 stolen rental cars and private vehicles in Karachi by October 2003. By then, the Trakker system had been installed in 12,000 Pakistani vehicles and attracted roughly 500 new customers.

per month, each paying up to $750 for installation and $17 monthly for service.28 Meanwhile, in January 2002 a thief stole a taxicab in Colorado Springs, Colorado, when the driver left the engine running while he went inside a 7-Eleven. In the first incident of its kind locally, a Yellow Cab dispatcher used the vehicle’s on-board tracking system to update police on the car’s location, and they arrested the culprit a short while later.29 During less than a year with integrated GPS/cellular tracking systems, Lieutenant Tim Stewart of the North Texas Auto Theft Task Force reported in 2004 that his agency had recovered more than $6 million worth of property, including more than 50 truck tractors and 75 trailers—many filled with stolen equipment or merchandise.30

Among the recreational uses for GPS, golfing became prominent. In 1997, Darryl Sharp’s Geodetic Services, Inc., began using GPS technology for three-dimensional mapping of premier golf courses in the United States and, by May 2002, had mapped 55 U.S. courses. Sharp estimated he would have lost $5,000–$6,000 per job without GPS but, with advances in GPS equipment, he had tripled his production. Under a five-year contract, videogame manufacturer EA SPORTS used Sharp’s data to make playing simulated golf on some of the country’s top-ranked courses stimulating and amazingly realistic for anyone with a personal computer or PlayStation. PGA TOUR later contracted with Geodetic Services to map courses for its new ShotLink scoring and statistics system that brought television or cyberspace fans closer to the game by reporting real-time information on every shot by every player in every tournament.31

Professional, amateur, and casual golfers all latched onto GPS-aided technology to improve their performance, and course managers enthusiastically supported the demand by purchasing GPS-equipped golf carts. In addition to recording exact yardage with each stroke and displaying actual yardage to the green, which aided club selection, personal GPS systems helped golfers maintain the pace of play. After courting by the electronics industry and a couple of years testing equipment such as the handheld SkyCaddie, the United States Golf Association finally permitted “distance-measuring devices, including GPS-based systems and laser range finders” by local rule starting in 2006. As demand for GPS-equipped golf carts surged in early 2006, UpLink Corporation, one of the three largest suppliers of golf-related GPS equipment, signed up 26 new courses with its system after a single trade show.

thereby generating $7.4 million in sales. UpLink technology allowed course managers to track every golf cart in their fleet, a financially important capability considering that golf-cart rentals yielded the largest source of revenue outside green fees at most courses. For example, a 2005 progress report from the mayor of South Bend, Indiana, mentioned that golf-cart revenue from GPS was more than $70,000.32

**Agriculture**

Use of GPS for precision farming (i.e., site-specific management) commenced in the early 1990s and rapidly took a variety of forms. These included planting or cultivating crops at night; locating weed, insect, and disease infestations; applying fertilizer or pesticides at a variable rate; preventing skips or overlaps when fertilizing; monitoring and mapping crop yield; and pinpointing crop damage due to hail or drought. John Ruth, chief executive officer of Amana Farms in Iowa, explained in a 1992 interview, “With GPS, we’ll be able to determine crop yield by the square foot and not by the traditional bushels per acre . . . . This will dramatically change the way farmers plant, fertilize, apply weed killers and harvest crops.”33 To further improve efficiency and increase the profitability of their operations, farmers also used GPS for detailed base-mapping of physical features such as borders, fence lines, wells, buildings, landscape features, irrigation canals or pipelines, and wetlands.34

Montana State University (MSU) began research and planning in 1986 for a GPS-assisted navigation system that would enable agricultural producers to apply variable amounts of seed and fertilizer exactly where needed to maximize crop yield in the most cost-effective manner. In August 1990 MSU researchers used the first GPS-guided agricultural fertilizer application system in a field trial near Power, Montana.35 Two years later, agronomist Mitch Schefcik and electrical engineer William Bauer

combined their expertise to devise a DGPS/Geographic Information System (GIS) system to vary the herbicide application rate on sugar-beet fields in western Nebraska, thereby increasing crop yield while satisfying government chemical application regulations. Experimentation by the Agricultural Research Service of the U.S. Department of Agriculture (USDA) found DGPS extremely useful for mapping initial, variable applications of nitrogen fertilizer and evaluating the effect on crop yields in irrigated central Nebraska cornfields during 1995. Improvement in nitrogen fertilizer management also offered the prospect of improved groundwater (i.e., drinking water) quality, something much desired by the U.S. Environmental Protection Agency.36

One expert estimated in 1994 that only 5 percent of U.S. farms, mostly in the corn-producing states of the Midwest, used GPS-derived reference points for soil-specific management, but the technology was “booming.” A study of soil-specific management in Stoddard County, Missouri, during that period showed reductions in fertilizer costs of $18.70 per acre with no loss of crop yields.37 By 2003 University of Florida researchers touted GPS/GIS technology’s great value for locating and managing site-specific crop losses (more than $77 billion worldwide in 1987) due to plant-parasitic nematodes.38 According to an Associated Press story in late November 2004, up to 15 percent of U.S. farmers had GPS-controlled tractors or combines and were saving as much as 5 percent in fertilizers and pesticides by using precision guidance systems. Farmers in Kentucky, where rolling terrain led to both high and low production in the same field, realized a cost saving of $30/acre by using GPS-enabled yield monitors. Meanwhile, under a NASA grant, researchers at Ohio State University worked to perfect a GPS-enabled tomato-picking robot that could significantly reduce labor costs on large corporate farms.39

To meet demand for greater accuracy, lower labor costs, and documentation of spraying, the USDA began in the early 1990s to explore GPS-aided navigation for precision aerial applications to control insects on cropland or rangeland. During the autumn of 1992, the Plains Cotton Growers Diapause Program in Texas had used a GPS flight guidance system from Satloc, Inc., to spray more than 450,000 acres of cotton for boll weevils. That application offered savings by eliminating the need for approximately 170 ground flaggers. Based on that program’s success, the USDA’s Grasshopper Integrated Pest Management (GHIPM) Project near Watford City in northwestern North Dakota tested a DGPS system in 1993 on a 6,400-acre (2,590-hectare) section of rangeland. Chief pilot Tim Roland for the USDA’s Animal and Plant Health Inspection Service, Plant Protection and Quarantine (APHIS/PPQ)

division subsequently remarked, “We’re just getting our foot in the door with GPS, but I’m so confident [about the] equipment that I’d recommend it to support any of our programs.”40 When the accuracy of Loran-C navigation proved inadequate to meet the parallel-swathing requirements of California’s Cooperative Medfly Project during 1993, Roland recommended DGPS guidance. In California’s war against the Mediterranean fruit fly, which could cause more than $1 billion in damage annually to fruit, nut, and vegetable crops, not to mention the loss of thousands of jobs, DGPS brought significant savings and provided a previously unavailable element of quality control to aerial treatments.41

**Disaster Relief And Recovery**

Use of GPS in conjunction with GIS, cartographic mapping, and other technologies proved beneficial in disaster relief and recovery efforts. After Hurricane Andrew devastated Florida in 1992, the Federal Emergency Management Agency (FEMA) contracted with survey crews to experimentally inventory the damage using GPS/GIS technology instead of the traditional, manual assessment that involved house-by-house interviews. Based on encouraging results from that experiment, FEMA, the U.S. Army Corps of Engineers, and a private contractor with GPS/GIS expertise formed a team in July 1993 to produce maps for disaster response, recovery efforts, and risk mitigation in the wake of severe Mississippi River floods that inundated more than 13 million acres, destroyed billions of dollars in crops, and left hundreds of people homeless. Following a GPS-equipped helicopter survey, a pair of two-person ground observer teams with GPS/GIS handheld receivers inspected and inventoried structures in approximately 75 communities south of Quincy, Illinois. More than 1,500 maps/data sheets were produced within a week of the teams’ initial transfer of data to the Corps of Engineers’ Rock Island, Illinois, base station. Prior to GPS/GIS, it would have taken a team of 50 people years to complete the same task. With the maps quickly delivered to FEMA decision makers, they began meeting with local officials and citizens to discuss assistance and requirements to rebuild above the 100-year flood elevation.42

When New York City officials faced the daunting cleanup of “Ground Zero” after the 11 September 2001 terrorist attacks on the World Trade Center, they found multiple applications for GPS. As Fire Department teams and others began the monumental task of sifting through the rubble to recover and manually catalog thousands of pieces of evidence at the crash site, which was also a crime scene, it became obvious the process was too time-consuming and too error-prone. To

---

automate it, the city gave a handheld device equipped with a GPS receiver and an attached bar-code reader to one person on each of the eight recovery units working at the 16-acre site at any given time. Searchers put a bar-coded tag on each significant piece of recovered evidence; scanned the tag to create an electronic record that included the exact location, date, and time; and selected an item description from a scroll-down list programmed into the handheld device. At the end of each shift, searchers placed their handhelds into a cradle to download their information to a central database, from which the city produced maps that helped investigators pinpoint where various kinds of vehicles, equipment, and personnel were when the buildings collapsed. The fire and police departments could analyze that information to improve their response to future emergencies.43

A second challenge related to the September 11 disaster involved learning how various buildings in a 10-square-block area surrounding the World Trade Center survived, because that knowledge would permit the design and construction of more damage-resistant structures. The solution lay in modification of a GPS/GIS software application for a Palm Pilot developed by Georgia Institute of Technology civil engineering professor David Frost and graduate student Scott Deaton. This handheld damage assessment technology, which Frost had conceived while surveying damage from a 1999 earthquake in Izmit, Turkey, allowed researchers to capture digital images and select an option from a list of damage descriptions, at which time the information was automatically linked to GPS coordinates. The collected data could be uploaded periodically to a single, spatial database. In approximately four days during mid-October 2001, Frost, Deaton, and master’s student Prateek Goel documented and mapped in nearly real time most of the structures in the study area. A team using more traditional methods would have taken at least a month just to enter all the data into a computer for mapping and analysis.44

Yet another GPS application in disaster recovery efforts at Ground Zero involved debris removal. Hauling away 1.8 million tons of debris efficiently became a top priority, because experience suggested this would be the most expensive aspect of the recovery effort. New York City’s Department of Design and Construction employed a team of contractors led by Criticom International Corporation of Minneapolis, Minnesota, to devise a GPS-based management system for debris removal. The contract team quickly assembled and installed commercial off-the-shelf components in 235 trucks and a control center, thereby creating a management system that integrated GPS-based positioning with communications, camera monitoring, and Internet data. This first use of GPS-based AVL to manage debris removal in a disaster

recovery operation contributed substantially to finishing the removal project four months earlier than originally predicted and at a cost of $750 million, far less than the $7 billion city officials initially estimated.\(^4\)

During and after Hurricane Katrina in August 2005, experts found further applications for GPS. Military pilots flew into the approaching hurricane to deploy GPS-enabled dropsondes, first used in 1996–1997, that helped scientists predict the strength, speed, and direction of the storm with greater precision than allowed by previous systems. After Katrina hit the Gulf Coast, the Urban and Regional Information Systems Association (URISA) GISCorps, a volunteer organization, went there to support U.S. Coast Guard operations by translating distressed survivors’ addresses or locations into GPS coordinates, which enabled dispatch of rescue helicopters. Within two weeks after the storm, major ports in the Gulf region reopened, due in large measure to Nationwide DGPS (NDGPS) allowing the Coast Guard to precisely reposition 1,800 buoys and fixed aids to navigation; the Army Corps of Engineers to survey and dredge 38 critical waterways; and commercial pilots to navigate even when they could not “read” silt-clouded waterways. The National Park Service used NDGPS to map areas rendered unsafe by hazardous materials and to mark safe passageways; the Department of Agriculture used it help locate disposal sites for animal carcasses and to map areas where blocked drainage demanded future clearing. Despite problems with keeping the NDGPS signal available in the aftermath of Hurricane Katrina, it proved crucial to relief and recovery efforts.\(^5\)

---

Timing

People generally think of GPS as a navigation system and, consequently, do not fully comprehend its usefulness in the dissemination of precise time, time intervals, and frequency. Because a GPS receiver location is established through simultaneous ranging of signals from several GPS satellites, every signal from each satellite includes time of transmission. Atomic clocks on every satellite ensure that system time is closely synchronized through cesium and rubidium frequency standards. By providing timing and frequency accuracies in the range of 100 nanoseconds and a few picoseconds, respectively, to receivers worldwide 24 hours a day, GPS quickly became a boon to specialists in a wide variety of fields ranging from science, satellite tracking, and industrial plant operations to power distribution, television broadcasting, and banking.47

The Bonneville Power Administration (BPA), which supplies about half of all electrical power used in the Pacific Northwest, began gradually integrating GPS technology into its various operations in 1988. Its ultimate goal was a GPS-based infrastructure for measuring voltage and current at selected generation and transmission sites and for time-tagging that information with microsecond precision to more effectively and efficiently stabilize the electrical grid, thereby minimizing system disturbances that potentially could cascade into major blackouts. In 1989, BPA began using GPS in its power-line fault location system and in solving problems associated with standard time distribution across the grid. Meanwhile, it started investigating GPS as a source of precise time for its phasor measurement units (PMUs), which computed the phase angle between points on various circuits to provide a good representation of the power system’s “health.” During 1991–1992, BPA tested two GPS-synchronized prototype PMUs on a 260-mile section of a main transmission link, the resulting data being more accurate and less noisy than comparable analog information. A new GPS-based Central Time System (CTS) with triple redundancy went into the BPA Dittmer Control Center in 1994. By 2005, BPA was touting its Wide Area Control System (WACS), a demonstration project that BPA engineers predicted could route $7.2 million worth of additional power—enough for 20,000–60,000 typical homes—from the Pacific Northwest to California and could prevent a system blackout costing more than $1 billion.48

The explosive growth of computer networks from the 1980s onward made high-quality time synchronization essential for proper functioning and for rendering failures more manageable. GPS-enabled time synchronization directly affected network operations in several key areas ranging from file time stamping and directory services to access security, log file accuracy, and fault diagnosis and recovery; it also affected applications in numerous areas from transaction processing and e-mail to software development and legal or regulatory requirements.49

At the beginning of the twenty-first century, financial institutions relied on millions of networked computers to execute billions of transactions per second involving extremely rapid changes in value. On 14 November 2001, for example, during the closing minutes of trading on the New York Stock Exchange, a single stock—Intel—averaged six transactions/second and as high as 20/second during intense trading. With traders frequently calling their brokering institution to dispute the recorded value of a particular transaction among countless others, computer-system clock resolution had to be less than the minimum transaction composition and transmission time—hence, 5- to 20-millisecond resolution. An international investment banking firm already had begun using a Palisade network time protocol (NTP) synchronization kit, introduced by Trimble Navigation Ltd. in 1999, to ensure simultaneous recording of transactions at its London, New York, and Tokyo offices. By mid-2002, the New York Stock Exchange, the World Bank, and other major financial institutions used Symmetricom (formerly TrueTime), Spectracom, or other corporations’ GPS-based NTP products to synchronize their computer systems at the required level of accuracy. Experimenters at Ireland’s University of Galway had installed Trimble’s newer Acutime 2000 GPS synchronization kit to create what they called a Stratum-1 (defined as micro-second accurate) NTP server that other European servers and clients used for time synchronization. So important had GPS become as a time-reference standard for the world’s aggregate financial network that the Heritage Foundation advised designating it a critical infrastructure.50

As wireless communication networks expanded at the end of the twentieth century, GPS receivers replaced less reliable timing technologies. So-called smart GPS antennas in base stations synchronized transmitter sites to precisely the same time, which prevented a

user from receiving the same cellular telephone, pager, or other wireless signal multiple times. In August 1996 at the Republican National Convention in San Diego, California, Pacific Bell Mobile Services (PBMS) implemented a new type of all-digital, wireless telephone network called personal communications service (PCS), which relied on relatively low-cost, GPS-based time synchronization. By early 1997, PBMS had begun building on that success by installing an identical capability in Las Vegas, Nevada.51

Wireless positioning and tracking also benefit immeasurably from the accuracy of GPS timing. A caller’s handset, for example, can be located by calculating and triangulating the time differences in arrival of its signal at cell towers whose positions are accurately known. In 1993, the Federal Communications Commission (FCC) took regulatory interest in extending enhanced-911 (E911) emergency service, including automatic location of a caller, to wireless mobile subscribers; in October 1999 Congress passed the Wireless Communications and Public Safety Act mandating that manufacturers incorporate E911 features in cell phones and, thereafter, the FCC stipulated that 95 percent of all new digital cell phones must have the automatic location identification (ALI) feature by 1 October 2002. The FCC later extended that deadline three years when wireless carriers appealed for more implementation time. At the beginning of 2005, Nextel Communications, Inc., was the only national wireless provider offering GPS services, and nearly all carriers doubted they could meet the end-of-year deadline for having 95 percent of their handsets upgraded to GPS-capable models. Although wireless E911 offered the prospect of improving the personal safety of millions of people nationwide, indications were that its availability would be piecemeal for years to come, and some citizens questioned whether the government, employers, spouses, or parents might misuse the ALI feature to infringe upon personal privacy and constitutional rights.52

Nothing about GPS could be more obvious than the rapid expansion of entrepreneurial activity and the veritable explosion of applications from the early 1990s into the first decade of the twenty-first century. One can measure that growth, at least notionally, in several ways: patent activity, manufacturers, employment, revenues, and sales. The number of GPS-related patent families (a family being a collection of related patents and published patent applications) grew internationally from less than 20 in 1988 to nearly 80 in 1991, with U.S. and Japanese corporations holding the most. Meanwhile, the DOD procured only 7,253 GPS receivers during 1986–1992 but zoomed to 19,086 receivers in 1993 alone. Firms that listed themselves as providing GPS-related goods or services totaled 301 in 1997 compared to 109 in 1992. North American revenues from GPS products in 1999 grew 21.1 percent from 1998, indicating that “an increasing number of end users in previously untapped markets” had begun accepting the new technology. Revenues worldwide from GPS user equipment sales totaled $3.39 billion in 1996 and rose to $6.22 billion in 1999; during the same period, the number of GPS industry employees worldwide increased from 16,688 to 30,622. With average prices for GPS products expected to decrease 7.4 percent annually through 2006, according to strategic research by the consulting firm Frost & Sullivan, the number of products sold for nontraditional applications in commercial and consumer markets would steadily increase. Among the five basic GPS market segments—land, aviation, marine, military, and timing—examined by Frost & Sullivan analyst Ron Stearns, the land-based segment alone accounted for 61.8 percent of total North American revenues in 1999, a statistic unlikely to change appreciably through 2006.

While the average price of GPS products continued downward in the new century, the number of units sold and total revenues advanced according to predictions. One estimate in 2000 put the number of GPS users worldwide at 1.5 million, with an economic impact of $6.2 billion. According to Frost & Sullivan, total revenues from the North American GPS equipment market alone amounted to $3.46 billion in 2003. A breakdown of that figure by end-user group—consumer, commercial, and military—revealed 52 percent, 40 percent, and 8 percent, respectively.

Recreational GPS devices constituted a huge market, with shipments rising from 3.2 million in 2002 to 5 million in 2003. Sales of portable navigation devices, used primarily for in-vehicle navigation, rose faster than projected in the United States from 300,000 units in 2003 to 550,000 in 2004 and about one million in 2005. Analyst Ron Stearns of Frost & Sullivan calculated the automotive portion of the consumer GPS business at $922 million, with estimated unit sales of 1.2 million for 2006; the addition of outdoor units for recreational users would send sales to $1.8 billion and more than 4 million units for 2006. Stearns expected combined annual sales for automotive and outdoor GPS units to reach 8.3 million, worth $2.7 billion in revenues, by 2010. As Bradford Parkinson, one of the founders of GPS, said in 1980, the “potential uses [of GPS] are limited only by our imaginations.”

In the earliest days of the Space Age, the U.S. government, for diverse and pressing policy reasons, elaborated the dual-use distinction. Their view became that space activities could in fact easily be delineated into peaceful civil purposes and clearly military purposes. This distinction in practice ultimately proved unsustainable but was especially convenient for arms control purposes beginning with the 1960s nuclear arms race. The dual-use concept has proven to embody several unanticipated effects which decisively and negatively impact future U.S. engagement in space commerce. This policy arose when the United States was effectively a monopolist with regard to space applications, but has different implications in a globalizing economy.

This paper analyzes, first, the rise of the dual-use concept and its general impact on civil/commercial space applications; second, how that situation changed with the cold war’s end and the lessening of security restrictions; and, third, the destabilizing economic effects that have arisen for the United States. This analysis focuses mostly on the American experience, but the dual-use concept proved particularly useful internationally with regard to slowing nuclear proliferation (the Nonproliferation Treaty)\(^1\); it was extended specifically in 1987 to space launch technologies with the Missile Technology Control Regime (MTCR),\(^2\) and more broadly with the “Wassenaar Arrangement on Export Controls for Conventional Arms and Dual-Use Goods and Technologies.”\(^3\) The latter is more wide-sweeping in its implications for transfer of dual-use technologies.

---

3. The Arrangement “complements and reinforces, without duplication, the existing regimes for non-proliferation of weapons of mass destruction and their delivery systems, by focusing on the threats to international and regional peace and security which may arise from transfers of armaments and sensitive dual-use goods and technologies where the risks are judged greatest. This arrangement is also intended to enhance co-operation to prevent the acquisition of armaments and sensitive dual-use items for military end-uses, if the situation in a region or the behaviour of a state is, or becomes, a cause for serious concern to the Participating States.” http://www.wassenaar.org/publicdocuments/Basic%20documents%202006%20-%20January.doc (accessed 15 October 2006).
The application areas focused on here include remote sensing (including weather), navigation, and communications satellite policies as the most obvious areas. Launch vehicle restrictions arose later than the others due to other factors. The changes occurring are not merely technological (i.e., improvement in the scale of images provided or accuracy of positioning information or enhanced communications) but are due to the fact that these largely military-initiated and -dominated sectors are becoming engines for economic growth and improvements in productivity. These applications are driving the commercial space sector to become more truly international in scope and operations. Early space visionaries often envisioned a world economically and politically integrated through the use of space applications, but that has not occurred because of national security restraints. Those security restraints have not vanished in the American case, but the global spread of technological competence regarding space technologies has removed the capacity of any single state to control these applications. The image projected by these changes is a cooperative, peaceful world but, for the United States, the political focus remains upon these applications’ potential to disrupt the U.S. economy and security operations.

**Dual-use as a Concept—Beginnings**

From the perspective of the late 1940s and early 1950s, at the cusp of the first Space Age, the dual-use concept was largely irrelevant because the operative assumption was that national space programs would be controlled and led by their military, with whatever civilian presence that developed being clearly subordinate one. The historical U.S. model for nonmilitary participation in space activities was the scientific expedition, such as Lewis and Clark in 1804, led by the military. Wernher von Braun’s famous series of articles in *Collier’s* assumed that the expeditionary model would continue. This concept faded in the 1960s but has been resurrected by U.S. Air Force space power advocates as a means by which to recapture their control over human spaceflight.

The purely civilian (especially commercial) aspect of space activities existed initially as a theoretical concept, despite Robert Goddard’s pioneering research on launch vehicles and early speculation by Arthur Clarke about communications

---

using Earth-orbiting satellites. The dominant reality became that the military (the Nazis and Soviets first, later the Americans) controlled the space technology development process, including funding of whatever launch technology was deemed useful. The military’s initial and primary interest focused on building more effective and farther-reaching weapons carriers. The wider possibilities for space activities were understood to exist and were the subject of preliminary analysis but all were considered within the paradigm of military control over any space-related technologies that might be developed. In fact, the original thought was that the military itself, through an arsenal system, would control production of such technologies. In the American case, however, the U.S. Air Force had extensive experience with contractors as technology producers under military supervision.

This contractor approach fit better with American ideological proclivities and provided greater flexibility for expansion and contraction of production, it being easier to lay off contractor employees than civil servants employed at an arsenal. One direct consequence of this approach was creation of an aerospace industry that was in place if and when military control loosened. The aeronautical side of the industry was an excellent prototype of a dual-use capability, although it was not thought of in those terms.

Embedded in the beginnings of the Space Age was the shadow of a dual-use concept, but even there the military remained dominant. The rise of space scientists was in part built around the reality that their initial value was as payload providers whose results had direct military relevance, especially improvement in communications and scanning capabilities through better understanding of the ionosphere and other environmental forces impacting radio wave transmissions at different frequencies and thus, by extension, military operations. Beginning with sounding rockets (high-altitude balloons were already in use), scientists found that the ability to leave the atmosphere even briefly to observe atmospheric and celestial events was truly liberating, opening up new vistas of scientific information and understanding. This original relationship explains why the first successful U.S. satellite launch carried a scientific experiment on-board whereas the Soviets’ first satellite was basically a transmitter in space, famously annoying the Americans with its repetitive beeping.

---

Concurrent with these military-dominated development efforts were research efforts within the communications industry exploring the use of satellites for facilitating global communications. These efforts were less publicly visible since the corporations involved, including AT&T (“Ma Bell”) and RCA, focused more on securing corporate economic advantage rather than the publicity sought by military services in their quest for Congressional attention. The 1940s and 1950s saw intense public campaigns by the military services to gain appropriations advantages relative to other services. In one sense, these private efforts were more realistically the harbingers of the dual-use concept because they were truly nonmilitary although communications satellites (comsats) possessed obvious military usefulness regardless of their origin.

Therefore, the dual-use concept is premised on a distinction that technologically had no reality but was considered politically critical if weapons of mass destruction (WMD) proliferation threats to world security were to be controlled. This nonproliferation effort focused heavily on missiles or rockets that could deliver weapons with no effective means of defense, although other applications came under similar constraints. However, the biggest political booster of this distinction, President Dwight Eisenhower, saw the dual-use concept’s value first with regard to his Herculean struggle to keep the U.S. budget under control (i.e., fiscally balanced). Eisenhower’s greatest political nightmare was that the United States would rush off in pursuit of glory in the heavens—a quest that he considered to be of little relevance security-wise.

On 4 October 1957, the first Sputnik launch led to an immediate and vociferous public demand for a U.S. space effort commensurate with that being apparently mounted by the Soviets. The public’s demand was fed by a Congress controlled by the president’s political adversaries. This situation further inflamed existing rivalries among the three U.S. military services, especially between the Air Force and Army; each eagerly sought to seize outer space as its new area of operations, just as they had previously squabbled over missile systems. With visions of large but separate competing military space programs dancing in his head, Eisenhower moved at once

to first, stop the interservice rivalry, and second, to cut off any military aspirations for pursuing human spaceflight, the most expensive and difficult of space activities. All of this domestic activity occurred against an international background where the global nuclear arms race loomed as an enormously expensive contest with no end in sight, except possibly Armageddon. Eisenhower was definitely not interested in having this nuclear arms race spread to the heavens, raining death from space. Plus, Eisenhower had severe doubts as to the military usefulness of outer space in terms of weapons.

Cutting off a potential interservice rivalry was politically easier than stopping the political rush to start a human spaceflight program. The Air Force had earlier been awarded control over land-based, long-range ballistic missiles; the competitive Army missile effort had been reduced to developing short-range or tactical missiles. This decision, however, had come only after years of bitter service infighting but was only put in place just prior to the first satellite launch. The president further confronted the political reality that his original effort to stymie the Army’s growing space efforts had come a cropper when the first Vanguard launch (a civilian program run by the Naval Research Lab) failed to leave the pad in December 1957—a perfectly dismal response to two Soviet successes with their larger and physically more impressive Sputniks. Prior to the Vanguard launch, the administration had hedged its bets by authorizing the Army Ballistic Missile Agency team, led by Wernher von Braun, to build a back-up launcher and satellite. This cobbled-together effort flew to orbit on 31 January 1958—Explorer I became the first U.S. satellite. The Army had argued in 1956 that it could orbit a satellite immediately but that option was rejected by the administration whose interests were different and more internationally focused. After the very public Vanguard failure, Eisenhower needed the political success symbolized by a successful Explorer launch, but von Braun’s and the Army’s larger space ambitions, including manned spaceflight, were not encouraged and were finally terminated.

Eisenhower’s resistance was premised on two views he held regarding a potential manned spaceflight race: first, the cost was too high given available national resources (remember, balanced budgets), and second, the Army could not be allowed to build up its space efforts in competition with the Air Force. The latter goal was comparatively easily achieved with the Army space program being shut down. That decision was bitterly resisted (almost to the point of active insubordination) but the president was adamant. That left the other piece—the question of a manned space effort run by the Air Force, the victor in the interservice space wars, with visions of a vast space effort to compete with the Soviets across the spectrum of activities.

The answer to Eisenhower’s latter problem came in the form of NASA, killing the proverbial two birds with one stone. NASA became the president’s stalking horse for removing the Air Force from the manned space arena. His view was that a manned space program run by a military service would be impossible to control in terms of budget growth because the military could always invoke military necessity in order to stymie any presidential efforts at budget control. The problem of military services end-running around the president to Congress regarding their relative budget share had been a continuing feature of domestic politics in the 1950s, especially since the other party, the Democrats, controlled Congress. Eisenhower’s great prestige as the commander of Allied victory in Europe helped him beat back some efforts, but military space activities were literally completely new—the president was considered no more expert than many others. Also, equally relevant was the U.S. desire to slow down the proliferation of nuclear weapons.

NASA became the stalking horse for achieving the president’s efforts—first to deflect Air Force ambitions and second to initiate successful arms control. The Air Force part was somewhat easier because, as a military service, it had to have an assigned mission in order to pursue a particular technology or approach. The decision was to transfer all manned or crewed spaceflight operations to the new agency, NASA, established 1 October 1958, leaving the Air Force out of the picture. The decision to make this move had two bases.

First, Eisenhower thought that a civilian agency would be more easily managed in terms of budget, lacking the political clout of the military services. In his assumption of NASA’s political weakness, Eisenhower was ultimately correct but mistaken in the short term—the Southern paladins within Congress (especially at the committee level) saw great opportunities for constituency service in terms of creating constituent jobs. When the Mercury program was approved despite Eisenhower’s misgivings, the door was opened for Congressional pork. With President Kennedy’s announcement of the Apollo program in 1961, NASA entered its Golden Age. Even in its relative political eclipse later, NASA has retained its usefulness for Congress as a source of constituent jobs.

19. Eisenhower’s resistance to government growth stymied Congressional leaders’ desire to create jobs. The creation of NASA presented the golden goose since Eisenhower was constrained by the political pressures to “do something about space.” New NASA Centers—Goddard Space Flight Center, Johnson Space Center, Stennis Space Center, and Kennedy Space Center—were established, while former NACA Centers—Langley Research Center, Glenn Research Center, Dryden Flight Research Center, and Ames Research Center—were upgraded and former Army space assets—Marshall Space Flight Center and the Jet Propulsion Lab—were acquired. All kinds of economic opportunities were brought to the southern United States, which historically had a severe deficit of such facilities and industries.
Second and more critical, by transferring manned spaceflight to a nonmilitary agency, the political opportunity existed for establishing outer space as an international sanctuary devoid of space-based weapons. This latter was extremely important for nuclear arms control purposes since, for the first time, the parties were not attempting to remove or restrict weapons already fielded; rather, they were attempting to deny weapons' initial entry into a location. The realm of outer space was defined as the common heritage of mankind, as stated in Article 1 of the so-called Outer Space Treaty:

The exploration and use of outer space, including the moon and other celestial bodies, shall be carried out for the benefit and in the interests of all countries, irrespective of their degree of economic or scientific development, and shall be the province of all mankind.

It was not to be an arena for direct military confrontation (Article 4):

States Parties to the Treaty undertake not to place in orbit around the Earth any objects carrying nuclear weapons or any other kinds of weapons of mass destruction, install such weapons on celestial bodies, or station such weapons in outer space in any other manner. 20

This perspective allowed an intense public space race competition between the two nuclear space powers to occur without necessarily leading to a military confrontation. 21 After the Cuban missile crisis in October 1962, the Soviets and Americans were both aware of how fragile the nuclear peace was—a fact which heightened their interest in decreasing confrontation potential. Thus, the race for the lunar surface could end with a clear winner, the United States, but without the hazardous outcome implied by an arms race.

Out of this mishmash of goals and motivations, the concept of dual-use arose as one primary methodology by which all space-related technologies could be evaluated as to whether they possessed significant military implications. This concept created a truly artificial distinction since the only real difference between military and civilian or commercial uses was, at its essence, user intent. The technology remained basically the same but its purposes varied. Military technologies were often more robust in terms of their survivability (i.e., military specifications or “mil specs”), but the central application remained the same for both.

21. In the interest of this nonmilitary space race, President Richard Nixon has been identified as reshuffling the Apollo crew schedule in order to ensure that a civilian was first to set foot on the lunar surface. Worden and Shaw, pp. 112.
Those with a more Machiavellian orientation might think that another important motivation was economic in that the dual-use concept permitted tightened political control over the dissemination of such technologies. The United States, for example, aggressively protected its monopoly over other Western nations with regard to space lift and any other space technologies they might develop that potentially competed with U.S. economic interests. For example, the launching of experimental communications satellites built by potential economic competitors was resisted until sufficient political pressure was brought to bear, one example being the French–German Symphonie comsat in 1974. Once that political barrier was broken, space communications technologies could now be sent to orbit by other nations, increasing their competitiveness with the United States. Success there, however, did not change the reality that military security-imposed limitations still affected their usefulness. In effect, these externally imposed technological disabilities distinguished the nonmilitary usefulness of the same technologies from the military—the essence of dual-use.

The impact of the dual-use distinction was very real economically because it imposed restrictions upon the usefulness of several space applications in competition with terrestrial-based competitors. Often discussions of space-based commercial applications ignore the existence of robust and established economic competitors. In fact, those competitors either directly or indirectly have impacted development of space applications. Early U.S. policy regarding comsats was driven by awareness that AT&T (the Bell system) and IT&T sought to dominate the new field of space-based communications. Controlling their monopolistic tendencies was a major factor in U.S. policy. Ironically, the pathway chosen solidified their critical role in the field’s future development since the initial satellite linkages were to their phone lines.

**DOMESTIC IMPLICATIONS OF DUAL-USE**

Dual-use space applications are, by definition, useful for civilians but their military potential renders their dissemination problematic. Simply put, during the cold war the domestic economic usefulness of such technologies was, as a matter of policy, subordinated to their potential as a threat enhancer for other nations. Therefore, strict constraints were imposed regarding how useful the application could be made or how widely it was disseminated. The universe of dual-use applications has become large and comprehensive, as can be seen in the various lists generated under the Wassenaar Arrangement.

The reality is that the United States has adhered to a much more restrictive view regarding dual-use technologies. Efforts at loosening those restrictions were underway in the 1990s but were partially reversed with regard to exports when allegations were made that China was stealing U.S. secrets. Congressional action in 1998 led to stricter enforcement of existing International Traffic in Arms Regulations (ITAR) by the Department of State rather than the Department of Commerce, which was deemed to be too willing to facilitate expanded international trade by loosening security restrictions. As a result, the United States returned to a policy similar to that during the cold war, when the trend was toward liberalized global trade of such technologies. Global trade in space applications expanded, but with less and less U.S. participation. American fears were that certain nations were stealing U.S. secrets—many with military implications, since the technologies involved were dual-use.

Launch technologies are the obvious dual-use technology; however, policy makers at first did not consider them critical simply because governments, through their militaries, controlled all the missile launch vehicle derivatives. In fact, not until after the Space Shuttle Challenger accident in January 1986 did a private launch sector come into view in the United States. This privatized sector flew legacy launch systems received from the government. Internationally, all major launch vehicles have been government-developed and -owned, even when they were spun off in the Arianespace context as a commercial corporation. Development of new launchers or upgrades of existing ones have thus far always been government-funded and ultimately government-controlled.

Efforts at purely private launchers have been more disappointing than successful, and even the successes (or near-successes such as SpaceX's Falcon series) get sucked into the government orbit. As a result, launch technologies did not pose an issue—the U.S. had an effective monopoly over space launch in the West while the Soviets controlled the rest. As launch technology spread in the form of ballistic missiles rather than space transportation, the United States and other nations concerned with weapons proliferation became alarmed at the fact that rogue and other unsavory states could readily acquire such militarily useful technology. Out of that concern arose the Missile Technology Control Regime (MTCR) in 1987 as the mechanism by which the dissemination of such dual-use technology could be regulated. MTCR attracted only limited support initially but its existence has

---

26. The Commercial Orbital Transportation Services (COTS) demonstration program involves up to $500 million for support of the International Space Station using either the Rocketplane Kistler or Space Exploration Technologies (SpaceX) as the supply vehicles.
been used to leverage other nations into compliance. India’s attempted purchase of cryogenic upper-stage engine technologies from Russia was derailed because of Russia’s need for Western support and investment to support the newly established Federation. The MTCR has not prevented the dissemination of missile technologies but, similar to nonproliferation treaties, has slowed the process. 27

Comsats

Communications satellites remain the lodestar of commercial space activity since their applications can generate significant revenues while also being militarily useful. Development of the field was dominated at first by the United States, both technologically and organizationally. Establishment of Intelsat was orchestrated to put the United States in the dominant position—it was defined as the monopoly over international satellite-based communications. In the early years, U.S. satellite manufacturers were favored, but once that monopoly was broken by the Europeans the United States argued that no comsat could be launched that operated outside the purview of Intelsat or later Inmarsat. In time, that broke down with the Canadian Anik satellites and later with regional systems such as Eutelsat and Arabsat, and finally in the commercial comsat vendors, the first being PanAmSat. The opening up of the comsat market made direct broadcast service (DBS) available, which individual consumers or groups can access directly without going through the gateways of the Intelsat system. 28 In addition, comsat companies became increasingly international in their ownership, which restricted U.S. ability to control communications in and out of certain nations. The international nature of these corporations made them less responsive to U.S. demands, although access to U.S. markets could be denied in retaliation.

In dual-use terms, comsats are available to an even wider group of users, including nations that the United States does not wish to have such access. For comsats, the dual-use argument was weaker and has largely been discarded except by the United States, since the idea of globalization implies and translates into more and more access to the worldwide communications net (never mind the World Wide Web, which is in fact a minor part of it). Proliferation of comsats and their methods of operation have completely undermined U.S. efforts at control since the United States no longer controls the manufacture or launch of such spacecraft. The Europeans are the strongest competitors, but other nations such as Japan and China are developing their manufacturing capabilities.

28. Ironically, PanAmSat was later acquired by a privatized Intelsat in 2005—a move symbolic of the changed policy environment.
Remote Sensing

The two areas most directly impacted by the dual-use concept are remote sensing and navigation. Clear restrictions were placed on all nonmilitary remote sensing satellites; weather satellites were the major exception, but even there the level of resolution was kept large (i.e., the aperture was kept at the half-mile [kilometer] level or higher rather than at the 3-foot [meter] or less level in order to deny any military usefulness to the images produced). In the late 1960s NASA began looking for space applications that would have social utility; remote sensing was one obvious application because the images produced had great social potential for social purposes, including environmental monitoring in particular.

With the empowerment of the environmental movement in the early 1970s, such a satellite became an obvious route to pursue. The Earth Resources Technology Satellite (renamed Landsat 1) was the result. The fact was that the satellite was deliberately kept less accurate than it could have been, ranging from approximately 131 feet (40 meters) to 246 feet (75 meters) with an approximately 115-mile (185-kilometer) swath depending upon the imager used. The effect was to thwart any attempt at commercialization of the Landsat or equivalent systems. The security-related fear was that a truly commercialized remote sensing approach would allow potential enemies to acquire detailed images at little cost even though they did not own space assets capable of doing the job or any space assets at all.

A series of struggles ensued over the next two decades, reaching their crescendo in the Reagan administration’s efforts to commercialize Landsat. That effort failed because, in reality, there was no large commercial market for the images produced—the images had usefulness but their large scale limited what could be observed. On a macro level, the images produced were useful but further advances in Landsat technology were effectively stymied by dual-use considerations. The pictures taken could be manipulated to improve the view, but that was of limited utility despite significant increase in resolution. The reality was that for two decades the remote sensing field was effectively a dead-end in terms of civilian applications. Efforts to open the field to commercial or other players took form in the passage of the Land Remote Sensing Act of 1992. This allowed the entry of commercial interests but did not change the security restrictions, which meant it remained a dead-end until that last part was put in place. The French, with their SPOT Image satellite, were the only international competitor; its images had somewhat greater resolution but also were not considered to be of military significance.

This national security dimension weakened in the 1990s as a consequence of two factors, the first Gulf War and the rising U.S. concern about international economic competitors. During the run-up to the 1991 coalition attack on Iraqi forces in Kuwait and Iraq, images from both Landsat and SPOT Image satellites were incorporated into military planning. Their large scale was in fact more useful for some purposes than the images acquired from intelligence satellites, which provided detail but no larger perspective. That usage meant that the security restrictions imposed over the years were in fact less useful than originally thought. Subsequently, in 1994, the Clinton administration effectively removed any restrictions on the image resolution being sought. That led to an explosion of applications for remote sensing licenses, although economic reality proved much harsher since most applicants lacked the financial resources to make their satellites happen. \(^{31}\) Ironically, the Department of Defense (DOD) now found this loosening-up to its advantage because the existence of such commercial options meant that the military did not have to build as large a remote sensing fleet as was earlier projected. This became particularly important after the Soviet Union’s collapse and the general decline in defense spending (partially reversed after 9/11).

The 11 September 2001 terrorist attack provided evidence as to this new operating environment: for example, in October–December 2001 DOD purchased all IKONOS images of Afghanistan so that others could not gain access. However, the commercial sector remains dependent upon the DOD for its survival given the competition with the aerial surveying industry. Improvements have occurred but delivery of space-based images is still too slow for many customers. Also, the problem of satellite revisit times to take subsequent images still advantages the aerial surveying industry. Further complicating the situation is the existence of a number of international competitors, including the Russians, using military-grade remote sensing data, the French, and, interestingly, the Canadians with their Radarsat system. Clearly, the technology has spread beyond the control of one nation.

Navigation

Navigation represents the clearest example of dual-use applications, since its pedigree was entirely military. What occurs is fairly straightforward; the military are obsessed with knowing their forces’ exact location (regardless of the enemy’s location). This is particularly true for the Navy, which operates beyond sight of landmarks. Establishing one’s position at sea awaited the development of the sextant where one shoots the stars to determine location and accurate clocks. Like a communications satellite, a navigation satellite provides a signal which, when

combined with signals from other navsats, gives one their exact location on Earth’s surface. The U.S. Navy pursued such a navsat system first with its Transit system in the 1960s, until the Air Force and Navy combined efforts to build what became known as the NAV GPS system.\textsuperscript{32}

Using this combination of radio signals and atomic clocks, the receiver can determine a location on the surface and/or in the air with great exactitude. This application was developed for positioning and search and rescue, although the civilian applications became quickly obvious. For the military, GPS reduced “friendly fire” incidents and other blunders due to the fog of war and facilitated development of GPS-guided munitions, greatly enhancing weapon effectiveness and lethality. The essence of the military transformation hinges on global GPS access.

The degree of precision provided was particularly sensitive because the U.S. military did not want to enhance the ability of America’s enemies to find targets employing the same GPS signal. Initially, the United States established two signals (now more)—one very accurate and precise for the military and other authorized users, and a second signal with a deliberate distortion (selective availability, SA) built into that signal.

In response to the shooting down of Korean Airline Flight 007 in 1983 when it strayed into Soviet air space, President Ronald Reagan had ordered the DOD to allow civilian access to the GPS signal. Opening the door to civilian use proved the equivalent to opening Pandora’s Box as the military, in time, lost control. Another aspect was that the DOD retained the capacity to completely deny the civilian signal under some conditions due to threat, imminence of war, or actual conflict. This SA function was controversial for non-U.S. users of GPS. Despite the U.S. military’s resistance, American and especially Japanese commercial vendors were relatively quickly able to create software that effectively negated the built-in distortion. In fact, the first large military conflict employment of GPS was during the first Iraq war in 1991 when, due to a shortage of military GPS receivers, the United States turned off SA so that commercial receivers given to the troops would work accurately. This decision further dramatized the DOD’s waning control over what was becoming a major commercial sector.

Afterwards, the navigation business exploded as more applications were developed that provided even greater precision. One powerful application was the timing function of the navigation satellites (each carries an atomic clock), which is used to control computer networks to allow greater efficiency in moving data across the globe. This enormously increased economic efficiency across large distances in moving information and money transactions. Absolute U.S. control over this critical business resource became a major controversy between the United States and other nations.

\textsuperscript{32} Handberg, International Space Commerce, chapter 6.
The Europeans, especially, saw SA and DOD control over the turnkey not as security-driven but as further attempts by the American monopolists to protect their economic dominance. The result, after some acrimony, was development of the Galileo satellite radio navigation system as an alternative to the GPS system. This Galileo system, the Europeans say, will not be turned off in a time of military conflict or imminent conflict, although that may not prove out in the long term as the Europeans come to see themselves as becoming more proactive globally, partially replacing the Americans. The DOD’s response was initially to reject any change but that view was overridden by President Clinton with the 2 May 2000 removal of distortion from the GPS signal. That decision attempted to forestall the Galileo program or at least make its development proceed more slowly. All such efforts failed, although splits within Europe over various Galileo issues have slowed development. In addition, the Europeans have solicited Galileo participation by non-European nations, including China, a fact that further feeds American concerns.

**Dual-Use and Its Implications**

The point being made here is simple: dual-use considerations directly and heavily impacted American domestic and international commercial space policy—international considerations are what drive the system even though the major economic impacts occur domestically. Those impacts are the unintended consequences of an American policy generated in an earlier period. No nation has been totally deprived of the capacity to acquire needed space applications because of the U.S. prohibitions, especially in the cases of communications, remote sensing, and navigation (and arguably rocket technology). The reality is that these restrictions have had more of an adverse impact on the U.S. economy than elsewhere. The United States is creating a bubble around its space commerce efforts by imposing security-driven restrictions that significantly blunt any U.S. efforts at competing economically in the global marketplace.33

Over time, the global spread of space technologies has eliminated U.S. capacity to determine to whom and for what uses the technologies will be available. That raises some interesting implications for the broader question of U.S. security policy. As a general policy concept, dual-use embodies several implications, the most significant of which is keeping the United States secure from its enemies by denying them improved militarily useful technology. What has slipped out of U.S. hands

---

33. The “bubble analogy” arose during the discussions of the original papers at the Societal Impact conference in September 2006; I regret not writing down who the author of the phrase was at that time. It is used here as shorthand for the isolation of American space industry from the global marketplace due to security restrictions. In other contexts, Joan Johnson-Freese has written and spoken extensively on the effects of the 1998 decision to reimpose security restrictions on U.S. technology exports, including space applications.
is the ability to control dissemination due to the multiplicity of players. Take any major space technology and you can find multiple providers outside the United States. This issue arose first in the 1980s when Japan, for example, was deemed more advanced in a number of militarily relevant technologies than the United States. That situation has grown worse. That translates into a situation in which U.S. space industry runs the risk of becoming less competitive and, by extension, falling behind possible military competitors in terms of application quality.

During the cold war there were two central players with their alliances; now there exist multiple combinations of players who may coalesce in opposition to the United States regarding various issues. The key problem is that the instruments through which America military power is exercised are now exceedingly vulnerable. One of the critical lessons learned, fortunately by analogy and not by attack, is that Earth-orbiting satellites are vulnerable to interference either directly through physical attack, or indirectly through manipulation of their operating programs or disruption of their signals. Proceeding along orbital paths, easily predictable by observation, means that satellites cannot hide. In fact, in orbital space, commercial satellites are growing even more vulnerable to disruption. Growing U.S. military dependence on commercial comsats and remote sensing satellites for critical tasks increases their vulnerability to disruption since commercial vendors find no reason to harden satellites or provide other means of protection. The costs are not justifiable for a commercial venture. The GPS system itself is capable of being jammed by any combatant more sophisticated than Iraq—their efforts in 2003 were not successful, but the way is clear.

The dual-use concept represented one effort at delaying American vulnerability to nations equipped with equivalent military technologies; the economic motivation has persisted even though the security justification has lost its potency. Both have lost their persuasiveness, especially the latter; American companies are now effectively excluded from many international economic opportunities regarding use of space technologies—strong, technologically sophisticated competitors are taking increasing market share in the different sectors of space commerce. The difficulty is that for the United States, change demands a rethinking of what is to be accomplished using space applications. Previously, U.S. policy was to bind others to the United States through security and economic ties, with the latter thought to be the more lasting. Those days are gone. Space history has seen the relative (not absolute) decline of American dominance with the entry of the Russians and the formerly excluded Chinese into the field, along with the rise of the Europeans and others to increasing prominence.
Conclusion

Dwight Eisenhower, along with others, effectively fabricated the dual-use concept to solve certain political problems that he otherwise felt would spin out of control. To that end, Eisenhower was successful and dual-use became embedded in U.S. policy thinking, although initially its implications were not entirely clear if the international environment were to change. Over time, the earlier question of security faded in intensity but not out of existence. The emergence of China as a potential rival led to an intensification of dual-use concerns, with the economic component much more publicly muted. Ironically, the result is that China has not been delayed by U.S. actions; the larger effect has been to severely cripple American space industry competitiveness more by inadvertence than by design. The two are now not mutually supportive, as in the beginnings when dual-use allowed the pursuit of American security and economic interests simultaneously. In a world of global economic competitions, balancing the values of economic competitiveness and security is no longer as simple or clear as before.
Chapter 19

Reconnaissance Satellites, Intelligence, and National Security

Glenn Hastedt

Policy arenas do not arrive on the scene full-blown, nor do they remain static over time. They grow and evolve. We are witnessing this today with homeland security. More than a half-century ago we saw it with national security. One way to conceptualize the dynamics involved in the development of a policy arena is as a stream of activity. Much like the origins of a river are found in the merging of smaller tributaries, a policy arena is the product of several different forces coming together. Typically they involve a definition of a problem, the emergence of a collection of institutions designated to address that problem, and the identification of a strategy set to solve the problem. Once under way, a river reinvents itself daily. The changes are not necessarily visible at the outset, but over time they become clear. External events, both man-made and natural occurrences, play their part in this evolution, but so, too, do the currents of the river and the life its waters sustain within it. International crises, accidents, bureaucratic politics, personalities, as well as new ideas and technologies are such driving and shaping forces in policy arenas. Finally, given enough time, rivers themselves disappear by either merging into larger bodies of water or vanishing into the ground as their water flow is reduced to a trickle. Changing perceptions of a problem or the proper way to address it may cause the first phenomenon to occur in a policy arena, whereas shrinking budgets and public apathy may bring about the second.

A key element of the policy stream that is national security was the development of reconnaissance satellites. They were not present in 1947 at the formal founding of national security as a policy arena—with the passage of the National Security Act—but they became an important force in its subsequent downstream development. Its effects can be seen in the identity and influence of the government agencies that make up the intelligence community; the manner in which intelligence was

thought about by policy makers; and the problems to which intelligence was put. In none of these cases were reconnaissance satellites the sole factor in producing these changes but in each case they played a major role.

**Formative Currents**

Four forces can be seen as having a formative influence on the development of the national security policy stream into which reconnaissance satellites would enter. The first was the problem of strategic surprise as symbolized by Pearl Harbor. This was the event that, in the minds of many, national security policy had to make sure was not repeated. The second force was the solution of greater centralization and cooperation at the national level among bureaucracies involved in foreign diplomatic, military, and economic policy. Pearl Harbor occurred in spite of warning; intelligence was present, but it was not recognized or acted upon. The inherent validity of this solution was reinforced by the wartime experience of ad hoc military centralization that came about out of the need to cooperate with the British. To bring this about, the 1947 National Security Act created the Central Intelligence Agency (CIA), the National Security Council (NSC), and unified the military services under a Secretary of Defense in a national defense establishment that would soon become the Department of Defense (DOD).

The third force was the de facto establishment of an intelligence community that was to work together to prevent another Pearl Harbor. Along with the newly created CIA the other founding members were the Bureau of Intelligence and Research (INR) at the State Department and U.S. Army, Navy, and Air Force intelligence. The final force that exerted great influence on the origins of American national security policy was the advent of the cold war. It presented the United States—and national security policy—with a clearly identifiable enemy in the Soviet Union and then a strategy—containment—around which policy makers could unite.

**Growth and Development of the Intelligence Community**

Today there are 16 organizations that officially constitute the intelligence community. Reconnaissance satellites played a central role in the formation of one organization and had a substantial impact on the development of two others. Reconnaissance satellites can be most directly linked to the establishment of the National Reconnaissance Office (NRO). President Eisenhower established the NRO by executive order in August 1960. It became operational on 6 September 1961, following an agreement between the CIA and the Air Force setting it up as a joint operation. The Air Force was placed in charge of launching the satellites and recovering the film capsules; the CIA was charged with developing the satellites. The director of the NRO was to be the undersecretary of the Air Force and
the deputy director was to be drawn from the CIA. Under terms of the initial agreement, neither the CIA nor the Air Force had to give up control over any of its reconnaissance satellite programs to the NRO. Instead, they would be merged at a higher level into a National Reconnaissance Program.

Reconnaissance satellites also played a role in creating the National Photographic Interpretation Center (NPIC), the predecessor of one of the newest members is the National Geospatial Intelligence Agency (NGIA). The original impetus for creating NPIC lay in a March 1960 suggestion by Secretary of Defense Thomas Gates that Eisenhower commission a study of the defense intelligence bureaucracy, describing it as an inefficient, huge conglomerate. Gates’s proposal languished until Francis Gary Powers’s U-2 reconnaissance aircraft was shot down. After this incident a Joint Study Group was formed that reported out just prior to the end of Eisenhower’s presidency. Among its conclusions were that the military was playing too prominent a role in the intelligence process, and it called for increased efficiency through the creation of NPIC. Both the CIA and DOD sought to run NPIC, with the DOD proposing the creation of a new unit and the CIA calling for the expansion of its already existing Photographic Intelligence Center. Secretary of Defense Robert McNamara acted on this recommendation and NPIC came into existence in 1961 as a community-wide asset in the interpretation of aerial photos. He also followed Eisenhower’s inclination to place NPIC within the CIA.

The third member of the intelligence community whose existence and development is tied to reconnaissance satellites is the National Security Agency (NSA). It was established by a secret executive order, National Security Council Intelligence Directive (NSCID) No. 6, entitled “Communications Intelligence and Electronics Intelligence,” on 15 September 1952. It formally came into existence on 4 November 1952. NSA is the successor organization to the Armed Forces Security Agency (AFSA). It was set up as the result of a Joint Chiefs of Staff Directive signed by Secretary of Defense Louis Johnson on 20 May 1949. Located within the DOD, the AFSA was assigned responsibility for directing the communications intelligence and electronic intelligence of the three military services signals intelligence units. In spite of this broad mandate, the AFSA had little power. For the most, part its activities consisted of tasks not being performed by the Army Agency, the Naval Security Group, and the Air Force Security Service—the units whose work it was to direct.

Walter Bedell Smith, President Harry S. Truman’s executive director of the National Security Council, found this state of affairs to be unsatisfactory. Particularly troubling was the failure of the AFSA’s performance during the Korean War when it was unable to break the Chinese and North Korean codes. His view was shared by General James Van Fleet, commander of the U.S. Eighth Army who complained that “[W]e have lost, through neglect, disinterest and possibly jealousy, much of the effectiveness in intelligence work we acquired so painfully in World War II.”

Smith wrote a memo in December 1951 calling for a review of communications intelligence activities, describing the current system for collecting and processing communications intelligence as “ineffective.” Three days later, on 13 December 1951, the National Security Council set up a committee (commonly referred to as the Brownell Committee after its chair, Herbert Brownell) to examine the matter. The Brownell Committee recommended strengthening the national-level coordination and direction of communications intelligence activities. The NSA was created as a result of these recommendations.

NSA got off to an inauspicious start. Although it successfully engaged in overflights of the Soviet Union, it lacked a capacity to provide intelligence on events elsewhere, such as the Suez crisis. Moreover, its efforts to break Soviet codes repeatedly met with failure. James Bamford goes so far as to speculate that in the 1950s NSA faced the prospect of going out of business and that a “produce or else” atmosphere had settled over the agency. Salvation came in two forms. First, there was support from President Eisenhower and his Board of Consultants along with an influx of funds in an effort to strengthen its code-breaking abilities. Second, there arose the perceived necessity of obtaining signals intelligence from Soviet missiles as a result of the launching of Sputnik in 1957. The initial solution to this need was the construction of Earth-based receiving dishes. The second-generation solution was the deployment of space-based satellite receivers. President Eisenhower gave his approval for the first launching of an ELINT satellite five days after Gary Francis Powers’s U-2 was shot down.

The story of the creation and growth of these national security organizations is more complicated than a straight-line response of policy makers to the development of reconnaissance satellites. It is one in which the existing currents of the national security policy stream heavily influenced organizational design. This comes through most vividly in the development of the National Reconnaissance Office.

The decision to create the NRO came years after explorations into the feasibility of space reconnaissance satellites had already begun. Not surprisingly, the Air Force was first to move in this direction. Officials were attracted by the potential power of long-range missiles and tasked the RAND Corporation to study whether they might be used to launch space reconnaissance satellites. Its report, “Preliminary Design of an Experimental Earth-Circling Spaceship,” was delivered in May 1946. Three others followed in 1947, 1952, and 1954. The last study was cosponsored by the CIA and recommended that the Air Force begin at “the earliest possible date completion and use of an efficient satellite reconnaissance vehicle.” RAND’s report formed the basis for General Operational Requirement No. 80, issued by the Air Force in March 1955, requesting proposals from the private sector for the development of a photographic reconnaissance satellite.

3. Ibid., p. 355.
Discussions were also under way at the presidential level. On 27 March 1954, President Eisenhower held a meeting with James B. Conant, James R. Killian, Jr., and other scientists that led to the formation of a study group under Killian’s direction to develop solutions to the problem of surprise attack. Its report, “Meeting the Threat of Surprise Attack,” was completed on 14 February 1955. Project 3 dealt with intelligence and was chaired by Edwin Land. In their briefings to Eisenhower, Land and Killian identified satellites as a promising system for collecting intelligence that would provide warning to the United States of an impending Soviet surprise attack. They also noted that the technology to realize this collection platform would take time to develop and suggested an interim technology: a high-flying reconnaissance aircraft. It would become the U-2.

Interest in space reconnaissance satellites led in multiple directions in the search for a technology to accomplish this mission. The favored Air Force option was to transmit photographs through a radio downlink. First known as WS-117L/Pied Piper and then Sentry, it would ultimately be known as the Satellite and Missile Observation System (SAMOS). The CIA advocated the mid-air capsule recovery system that had been rejected by the Air Force. It became known to the world as Discoverer and to those involved in intelligence collection as CORONA. Competition continued even after a February 1958 Eisenhower meeting with Killian and Land that reviewed the difficulties the Air Force was having in developing its reconnaissance satellite. As a result of that meeting, Eisenhower decided to give the CIA primary responsibility for developing a reconnaissance satellite. The Air Force did not, however, stop work on its preferred option. It proceeded with its Sentry system.

The search for an appropriate technology to use for satellite reconnaissance went hand-in-hand with efforts to devise an organizational structure within which to house it. The search did not begin with a clean slate. A stream of activity was already in place and had left a legacy into which organizational thinking would enter. When the earlier decision had been made to build the U-2, Eisenhower determined that the CIA—not the Air Force—would be in charge of the operation. There was nothing automatic about this. Director of Central Intelligence (DCI) Allen Dulles was a firm believer that human intelligence gathering should be at the core of the CIA’s covert operations. He had shown little interest in the project earlier in 1954 and is described as “accepting the inevitable” in later accepting CIA jurisdiction over it. This came after Edwin Land wrote a letter to him strongly urging the CIA to take the lead in the CL-282 Project that would become the U-2. Land wrote “I am not sure that we have made clear that we feel there are many reasons why this activity is appropriate for the CIA . . . . We told you that this seems to us the kind of action and technique that is right for the contemporary version of the CIA: a modern and scientific way for an Agency that is always supposed to be looking, to do its looking.”

---

Richard Bissell, a special assistant to Dulles, was given the assignment to develop the U-2, and a special standalone unit within the Directorate of Plans, the Development Projects Staff, was created to manage it. This decision did not put an end to bureaucratic jockeying for control over the U-2 program. Air Force Chief of Staff General Nathan Twining believed that the Strategic Air Command (SAC) under the direction of General Curtis LeMay should be in charge of the U-2. In the spring and summer of 1955, he lobbied for such a change, only to have SAC settle for limited participation in the U-2 program.

Given the speed with which the U-2 was developed and became operational, it is not surprising that Eisenhower again turned to Bissell and his Development Projects Staff in 1958 as the lead organization after the decision was made to go ahead with the Discoverer/CORONA reconnaissance satellite program. Beneath them, the CIA and Air Force continued to go their separate ways. Each encountered internal organizational problems. Within the Air Force, responsibility for space satellite reconnaissance shifted from unit to unit with dizzying frequency. At different times it was the responsibility of the Air Force and the Advanced Research Projects Agency, sometimes leaving the Air Force with responsibility for little more than supervising global surveillance studies and at other times being in charge of total control over satellite reconnaissance programs.

At the CIA a different sort of organizational problem arose. Bissell was appointed Deputy Director for Plans, putting him in charge of all CIA covert operations. In moving into this new position in 1959, he took with him control over U-2 and CORONA, effectively removing them from the Development Projects Staff. This move alarmed Killian and Land, who saw covert action and human espionage as very distinct from espionage based on science and technology. Moreover, they were concerned that within the CIA there was now insufficient attention being given to science and technology issues which were now found in virtually all quarters of the CIA.

The establishment of the NRO as an operational unit in 1961 did not end the conflict between the CIA and Air Force over control over reconnaissance satellites. Where the CIA saw the Air Force and the NRO as one and the same, and as together trying to force it out of the satellite reconnaissance business by taking over its successful CORONA program, the NRO saw itself as a truly national intelligence agency having a small Air Force component. Over the next several years, each body recommended that the other all but go out of the satellite reconnaissance business. In November 1962 Air Force officials proposed that many (if not all) CIA reconnaissance projects should be transferred to the Air Force and that all program functions should be consolidated within the NRO. The CIA would later counter with a proposal to eliminate the NRO with “all research, preliminary design, system development, engineering, and operational employment” going to the CIA. It was not until April 1965 that a truce was achieved with DCI Admiral William Raborn and Secretary of Defense Cyrus Vance agreeing to a formula whereby the Secretary of Defense had ultimate responsibility for managing the NRO, including its budget.
and choosing the director. The DCI was to have responsibility for determining collection priorities and the CIA was to continue to be responsible for CORONA and the development of new systems once the concept was selected.

A NEW DECISION-MAKING ENVIRONMENT

Reconnaissance satellites not only helped to create new organizations or transform existing ones; they also altered the shape of the national security policy decision-making environment into which they flowed in three ways. A first change was to complicate and accentuate the managerial challenge facing the DCI. From the outset this individual was simultaneously the head of the CIA and the head of the intelligence community. And from the outset the DCI struggled to transform this grant of authority into something meaningful. Not only was the CIA a new organization but also the other founding members of the intelligence community were located in existing organizations. This would also be true of all others who later joined the intelligence community. This created an immediate point of contention between a DCI trying to forge a community wide policy and intelligence officials in these agencies who were part of organizations that did not always agree with this policy.

This problem was noted by the First Hoover Commission in its 1948 report. Its subcommittee on national security policy, the Eberstadt Committee, wrote that “[T]he Central Intelligence Agency deserves and must have a greater degree of acceptance and support from old-line intelligence services than it has had in the past.”7 Singled out as still unsatisfactory were relations between the CIA and G-2 (Army intelligence), the FBI, the Atomic Energy Commission, and the State Department.

As we have seen, the development of reconnaissance satellites quickly elevated the Air Force to the position of the CIA’s primary antagonist. Conflicts of interest also developed between intelligence agencies involved with the operation and development of reconnaissance satellites and the analysis of their products. NSA and NRO have quarreled over the proper mix of space-based systems, with NRO consistently supporting a more costly systems mix. In addition to competing with NSA, NRO also solicits funds directly from the military services through the promise of tactical intelligence that will support their missions. In an effort to resolve these conflicts the National Imagery and Mapping Agency (NIMA) was created in 1996 by bringing together several offices including NPIC. The creation of NIMA did not end bureaucratic disputes over imagery intelligence. The CIA’s Directorate of Science and Technology sought to regain control over functions lost to NIMA, while the NRO continued to have program and budgetary control over ground station and mission control elements of space-based imagery.

Second, the development of reconnaissance satellites also contributed to changing the balance of power among the members of the intelligence community by directing spending toward some agencies and away from others. Current estimates are that by 9/11, 85 percent of the intelligence budget lay beyond the control of the CIA. The overwhelming portion of this money went to DOD intelligence agencies, most notably NSA and NRO. The inability to control intelligence budgets beyond the CIA, and especially those in the DOD, became a constant issue in studies of intelligence reorganization and a point of debate in the creation of the Director of National Intelligence position. The 9/11 Commission’s proposal to create a Director of National Intelligence gave this individual significant budgetary powers over all intelligence community funds. As passed, the legislation accepted the view put forward by the DOD that this power should be limited.

Third, reconnaissance satellites contributed to the development of collection “silos.” Under ideal conditions, the relationship between analysts and collectors is one where analysts identify intelligence needs and collectors translate those needs into specific targets. Instead, a system has developed that is driven by collectors and the technology they control. Additionally, the information gathered by these collection systems, more often than not, is treated in a proprietary fashion. Its distribution is controlled and limited. As a consequence, intelligence from different collection sources tends not to merge together in a constructive fashion so that analysts can provide policy makers with answers their questions; instead, it comes forward in competing streams from different collection silos.

Even in their early stages, the managerial impact of these changes was recognized. In 1971 the Schlesinger Report, an inquiry into the operation of the intelligence community, began by stating what it saw as two disturbing trends in the operation of the intelligence community. The first was the “impressive” rise in cost and size. The second was the inability to translate those two features into improved intelligence products. Among the factors it cited as responsible for this state of affairs were competition between collection units that has led to unproductive duplication and unplanned growth, which has led to a series of compromise solutions. It concluded that the main hope for realizing any such improvement lay in a “fundamental reform of the intelligence community’s decision making bodies and procedures.” What was needed were “governing institutions.”

**View of Intelligence**

Reconnaissance satellites fit uneasily into the ongoing thinking about the role of intelligence in the national security process. This relationship was anchored in two guiding assumptions. First, the purpose of intelligence was to prevent strategic

---

surprise. The development of reconnaissance satellites fit comfortably here. Second, the collection of intelligence was thought about primarily in human terms: covert action and espionage. Reconnaissance satellites ran counter to this assumption and would ultimately undermine this tendency to equate intelligence collection with human intelligence. In the process it would lend an aura of legitimacy to espionage that had never existed.

Reconnaissance satellites, along with their predecessor, the U-2 reconnaissance aircraft, were quick to demonstrate their value as instruments for preventing strategic surprise. Beginning in the mid 1950s, political forces within the U.S. intelligence community (led by the Air Force) raised the specter of a bomber gap in which the Soviet Union held a decided and threatening lead over the United States in the development of a large strategic bomber force, creating an American vulnerability to a surprise attack. U-2 overflights in 1956 provided visual evidence that this gap did not exist. Satellite reconnaissance photographs would do the same just a few years later when they provided visual evidence that led to a repudiation of the charge that a missile gap now existed.

The change in emphasis from human to technological intelligence collection can be traced both to failures of the former and successes in the field of photographic reconnaissance. The late 1940s and 1950s were the heyday of covert action against procommunist regimes around the world and efforts to place agents inside the Soviet Union and behind the iron curtain. The failed 1961 Bay of Pigs invasion marked the end of that period, calling into question the credibility of the CIA and its top leadership in the area of covert action. Eighteen months later, the Cuban missile crisis cast doubt upon relying on human intelligence to prevent strategic surprise. U-2 photographs provided the conclusive proof needed by the Kennedy administration, confirming that Soviet missiles were being installed in Cuba. Classical human espionage in Cuba had been unable to provide such intelligence.

There is, however, one aspect of intelligence that the increased prominence of information (especially photographic images) gathered from U-2 overflights or reconnaissance satellites did not change. It did not provide a silver bullet that ended policy debates over how to interpret intelligence. Army and Navy intelligence, along with the CIA, saw in early U-2 photographs evidence that future Soviet ICBM launching sites would resemble the testing site at Tyuratam, Kazakhstan. The Air Force disagreed and argued that no particular configuration could be assumed. In fact, the arrival of the U-2 photographs may have accentuated the problem of interpretation. Photographs were compelling and easily understood by policy makers. At the same time, they were too compelling and lent themselves to self-deception and wishful thinking.

EMERGENCE OF A NEW POLICY AREA

The success of first aerial reconnaissance and then satellite reconnaissance in determining Soviet weapons capabilities helped to usher in a shift to thinking about the fundamental purpose of intelligence and national security policy more broadly. Although a concern for preventing a surprise attack never totally disappeared, it was now joined by a concern for developing a framework for managing U.S.–Soviet superpower relations.

Historically, attempts at reducing international tensions were predicated on two assumptions and frustrated by one overriding concern. First, military cooperation among enemies had to be preceded by some form of political accommodation. Second, such cooperation was negotiated into existence by a treaty or similar international agreement. Even when these were realized, a reduction in tensions could be frustrated by the fear of cheating.

By the late 1950s and early 1960s, the cold war had become recognized by all as an international fact of life. No abatement was in sight. Efforts to formally negotiate cooperation, such as the Open Skies proposal, had not met with success. The development of huge nuclear inventories also made it clear that neither side in this struggle could hope for a military triumph over the other at anything except a tremendous cost. The Cuban missile crisis reminded policy makers and the public that conflicts between the two superpowers were not a thing of the past and that they held the real potential for leading to war. Together, large nuclear inventories and the danger of accidental war made it increasingly clear to policy makers in both countries that even though they were enemies they had an interest in reducing tensions.

Steps such as the hot line linking Moscow and Washington were post–Cuban missile crisis moves in the direction of seeking to have a more peaceful and stable relationship without a formal treaty of any kind. This was followed later by interest in negotiating a reduction in the number of nuclear weapons through the Strategic Arms Limitations Talks (SALT I). Still, the problem of cheating remained and it was accentuated by the recognition that the United States and Soviet Union remained enemies. Where political considerations made on-site inspections impossible, reconnaissance satellites offered a more reliable and politically acceptable method for ensuring that each side lived up to the SALT I agreement. They did not infringe on state sovereignty in a traditional sense because the principle of nonterritorial spaceflights had been established in 1955, when the Eisenhower administration and the Soviet Union both announced plans for launching of International Geophysical Year satellites. Reconnaissance satellites also operated unilaterally; they did not require the formal cooperation of other states.

Their ability to verify behavior and act as a stabilizing force in world politics was dependent, however, on three conditions being met. First, both sides had to possess this satellite capability. The first Soviet reconnaissance satellite was launched in April 1962 and it appears that the Soviet Union reached this capability in 1963.
when Khrushchev began to publicly refer to such a capability. Second, both the United States and Soviet Union had to agree not to try and shield information from the reconnaissance satellites. This was accomplished in SALT I with the agreement on noninterference with national technical means of verification. Third, neither side could have a serious anti-satellite capability. The U.S. moved its policy in this direction in late 1962 when the DOD “reoriented” or canceled the Air Force’s Satellite Interception Program. The Soviet Union ceased its anti-satellite testing in 1971, on the verge of the SALT I treaty.

As we asserted at the outset, policy arenas are constantly evolving and changing as they move forward in time. So it was with conflict management. The ability of reconnaissance satellites to perform their verification function was dependent upon more than technology. As the political foundations of détente began to crumble in the late 1970s, unilateral actions on the part of the Soviet Union and United States began to undermine this verification function. Talk of winning nuclear wars appeared in official pronouncements; definitions and standards of verification were now openly debated; and both sides moved once again to test and develop anti-satellite capabilities. Currently the development of a strategy of preemption threatens to reduce the stabilizing influence of space reconnaissance satellites by making them early targets for military action.

A spinoff from the employing space reconnaissance satellites as a key element in the development of a conflict management framework for stabilizing U.S.—Soviet relations was the need to obtain ground stations to receive the information they collected. Here again, reconnaissance satellites did not create a new national security issue area as much as they added a new element with its own unique dynamics into an ongoing policy stream. The early 1950s saw the United States establish ground stations to support the gathering of electronic intelligence and to monitor Soviet nuclear tests from Great Britain and Norway. More politically sensitive ground stations were set up in Turkey and Iran.

The 1966 decision to rely upon satellites in geostationary orbit to detect Soviet missile launches required the construction of ground stations outside of the United States. The most advantageous site for such a station was Australia. Two would be constructed, one at Nurrangar and the other at Pine Gap. Over the next few decades this decision became the focal point of conflict within Australia and consequently an occasional issue in U.S.—Australian relations. One point of contention was the potential such a station created for making Australia the target of a nuclear attack. This issue was raised in Australia’s Parliament by the opposition Labor Party. Another

issue (and one that resonated well in Australia) was the secrecy surrounding the project. Gough Whitlam, the head of the Labor Party, raised this point in Parliament, asserting that while it was right for Australia to cooperate with the United States, it was wrong for the Australian government to withhold information on the project from Parliament and the public. Relations between the United States and Australia became particularly touchy during and immediately after Whitlam’s short-lived Labor government of 1973–1975. Whitlam had made it known that he wanted to review the future of American bases on Australian territory. In 1975, with his government locked in a budget crisis, Governor-General Sir John Kerr removed Whitlam from office and replaced him with Conservative leader Malcolm Fraser. Left-wing forces in Australia asserted that Whitlam’s removal from office was a CIA-engineered coup.

**The Post–Cold War Era**

The impact of reconnaissance satellites on intelligence and national security policy did not end with the passing of the cold war. Instead, the policy stream in which reconnaissance satellites now operate has altered course. In most cases the changes now evident were present as ripples in the latter part of the cold war, and subsequently have gained in strength. As was the case with the cold war national security policy stream, we can expect reconnaissance satellites and the content of this policy to affect one another. Several indicators already point in directions where this interactive effect is likely to be most pronounced over time.

One notable and already evident area of impact on national security policy is the increased use of reconnaissance satellite imagery for tactical military purposes. Satellites had provided support for military operations on a limited scale prior to the end of the cold war, in the 1986 bombing campaign against Libya, and Operation Just Cause in 1989. A quantum leap in the reliance on satellites took place in 1991 with the Persian Gulf War. Satellite intelligence was used to provide warning of SCUD attacks, target Patriot anti-tactical ballistic missile rockets, provide weather data, aid with land navigation and aerial bombardment, and serve as a communication channel. The war against terrorism also has seen a heavy reliance upon satellite imagery and electronic intelligence in efforts to trace the movements of key terrorist leaders and identify targets.

This changed role for reconnaissance satellites (away from strategic intelligence to tactical intelligence) has brought with it the necessity for adjustments by both the providers of this intelligence and its recipients. In the 1991 Persian Gulf War, postmortems noted that distribution of intelligence was a significant problem and that some senior commanders were unfamiliar with the capabilities and limitations of U.S. intelligence systems.13

A second emerging change is that the United States and Russia no longer have a monopoly over satellite reconnaissance. Two sets of competitors with different interests have emerged. One group is made of states that have begun to pursue a reconnaissance satellite capability for national security reasons. Foremost among them is Israel, which in the past chafed at the inability or unwillingness of the United States to provide it with satellite images. It launched its first reconnaissance satellite in April 1995. Japan has also acted on regional security concerns to launch reconnaissance satellites; its first launch was in March 2003. Germany, Italy, Spain, India, and Pakistan are also moving in this direction. Down the road, the ability of other states to use satellite reconnaissance for self-defense or offensive maneuvers reduces the ability of the United States to use reconnaissance satellites as a conflict management tool.

Also emerging as competitors are commercial reconnaissance or observation satellites. The first U.S. commercial observation satellite was launched in 1972. France followed in 1986, as did the Soviet Union one year later. The increased technological sophistication of commercial reconnaissance or observation satellites effectively makes them dual-use systems with commercial and military applications. They have the potential for revealing sensitive information that states would otherwise like to keep secret, such as when SPOT and Landsat photos showed the level of devastation at Chernobyl. They also have the ability to allow states to challenge the United States’ interpretation of events. This occurred in 1996 when France did not support a cruise missile strike on Iraq because imagery at its disposal did not show a significant Iraqi troop movement into Kurdish areas. Commercial observation satellites may also serve as auxiliary or adjunct intelligence services for states. This occurred in the war against terrorism in Afghanistan when NIMA bought exclusive and perpetual rights to all imagery taken of Afghanistan by the Ikonos satellite.

A third emerging trend is a broadened demand for the services of reconnaissance satellites that transcend the traditional dividing line between national security and non-national security policy issues. These include monitoring of environmental conditions such as droughts and natural disasters, and narcotics trafficking and potential terrorist targets. NIMA was tasked to provide support to the 2002 Winter Olympics in Utah and the 2004 Summer Olympics in Greece. The National Geospatial Intelligence Agency supported Hurricane Katrina relief efforts by providing information to the Federal Emergency Management Agency on affected areas from U.S. government satellites, commercial satellites, and airborne reconnaissance platforms.

16. Lowenthal, Intelligence from Secrets to Policy, p. 68.
In looking to the future impact of reconnaissance satellites on national security policy, the key questions may not be technological in nature as much as they will be contextual. Three features related to intelligence are of particular importance. First, during the cold war the intelligence challenge largely was defined in terms of unearthing secrets. Today, the challenge is more to unravel mysteries. Searching for secrets involves searching for something that is knowable but being denied to you. Mysteries are open-ended and evolving. Reconnaissance satellites proved their worth in revealing secrets; solving mysteries may be a different matter. Photographs could not establish whether Saddam Hussein had weapons of mass destruction or what his intentions were. Years of electronic and communication intercepts have not clarified the nature of the global war on terrorism.

Second, a strong current of reform in intelligence circles pertains to the need to integrate open-source intelligence into both collection and analytic processes. During the cold war, secret intelligence gathered by reconnaissance satellites was combined with secret intelligence collected by human sources to provide the basis for intelligence analysis. The possibility now exists that secret information gathered by reconnaissance satellites and other sources will be combined with information from public sources to produce intelligence products. One consequence may be a reorientation among intelligence agencies and a shift in the balance of power among them.

Finally, should terrorism continue to provide the main context for American national security policy, a readjustment in the place of reconnaissance satellites in the strategy to fight it may come about. Conceptualizing the conflict with terrorism as a war works to place military action at the core of an anti-terrorism strategy. It also favors reconnaissance satellites over other means of intelligence collection for bureaucratic and historical reasons. Should the conflict with terrorism come to be viewed in a criminal justice context, then intelligence from reconnaissance satellites is not so favored. Instead, policing strategies will be most heavily relied upon, and intelligence gathered by reconnaissance satellites will be read by analysts and consumers with different notions about how to use intelligence and what type of intelligence is most valuable.

**Conclusion**

Reconnaissance satellites have contributed in a number of ways to the changing face of intelligence within the national security policy arena. Their influence has been considered not so much as an isolated variable forcing change, but as one force

of many. This is because the national security policy arena into which reconnaissance satellites entered already existed as a stream of activity. Reconnaissance satellites entered this stream and helped change it. The impact of reconnaissance satellites on intelligence and national security policy does not end because the cold war is over. They will continue to shape intelligence and national security policy as this policy arena moves further downstream.

In the cold war period, two particular areas of impact were, first, on the changing fortunes of the CIA within the intelligence community, and second, on the development of a framework for managing superpower cold war relations. From the outset, the CIA faced challenges in establishing a position of leadership within the intelligence community. The advent of reconnaissance satellites, combined with the CIA’s own failings in the areas of covert action and human espionage, helped bring into existence an intelligence community whose key organizational players lay beyond its effective control and whose key intelligence collection methodologies were rooted in science and technology. The resulting situation proved to be a mixed blessing. On one hand, reconnaissance satellites produced unprecedented insight into the national security policies of the Soviet Union. On the other hand, collection silos arose, human intelligence capabilities declined, costs rose dramatically, and managerial problems festered.

Reconnaissance satellites also helped usher in an era of conflict management between the United States and Soviet Union. They were instrumental in transforming an area of competition into one of conflict management by providing each side with a largely unilateral means of verifying the behavior of the other. Students of international relations have long commented that it is the absence of trust and the fear of cheating that makes cooperation so difficult in world politics. Reconnaissance satellites showed that, with proper motivation, technology can provide a mechanism allowing states to cooperate in the absence of trust. The changed atmosphere of the cold war during the Reagan administration also showed the limits of technology as a proxy for trust.
Section V

Social Impact
The methods and concerns of social history, or what is often referred to as the “New Social History,” came to dominate the study of U.S. history during the 1960s and 1970s. To this day, practitioners in the field continue to shape the history curricula at major universities and the content of leading professional journals. Despite the popularity of social history, it has had almost no influence on the practice of space history. Social historians have ignored spaceflight as a topic of study and space historians have looked infrequently to social history for ideas and inspiration. Perhaps the reason for this divide rests on how each field addresses a fundamental methodological question, namely: What activities, events, and individuals are worthy of inclusion in the historical record? Whereas social historians see matters of historical importance in the lives and experiences of ordinary people, space historians, following a tradition established by nineteenth-century Scottish historian Thomas Carlyle, tend to look to the other end of the social ladder for material and inspiration—to the actions and accomplishments of cultural elites.2

Although ordinary people remain bit players in space history, the field has not been a staid backwater of historical analysis. With the emergence in the past two decades of what former NASA chief historian Roger Launius has labeled the

1. The description of the field as “new” is to distinguish it from an older body of social history, often derided as “pots and pans history,” that chronicled domestic practices and local cultural life without paying attention to larger socioeconomic issues, such as the influence of race and gender on the organization of work and social life. Alice Kessler-Harris, “Social History,” in The New American History, Eric Foner, ed. (Philadelphia: Temple University Press, 1990), pp. 163–165.

“New Aerospace History,” space historians have moved away from hagiographic approaches that uncritically relate tales of inspirational individuals, revolutionary technologies, and momentous political decisions. The New Aerospace History includes an impressive range of topics, from studies that explore the role of spaceflight in American culture to those that illuminate the broader political, diplomatic, and cultural context in which political leaders have made major decisions regarding federal space policy. The field, nonetheless, remains focused on elites and artifacts.

The central question of this conference—the impact of spaceflight on society—is itself an indication of the gulf separating space history from both social history and mainstream historical practice. The concept of societal impact is problematic to the extent that it is based on an assumption that the influence of spaceflight on society is more worthy of analysis than other conceptualizations of the relationship, such as the influence of society on spaceflight or the mutual shaping of spaceflight and society. By framing the conference with a unidirectional model of historical change (from government to society; from technology to social change), the conference organizers (among whom I was one) unwittingly encouraged presenters to focus on the production end of spaceflight (the accomplishments and products of government space activities) and to ignore the individuals and social groups who ostensibly were “impacted” by space activities. As presented in the program for this conference, society appears as a monolithic, homogenous blob that reacts as a singular entity to new capabilities and ideas generated from federal space activities. Society does not

4. Historians who consider the role of spaceflight in popular culture—a topic of recent and growing interest—tend to focus more on the spectacle of space technology and its presentation (in museums, movies, books, television, etc.) than on the spectators. The emphasis on ideas and meaning is welcome, but to the extent that such works substitute the perspectives of spaceflight elites and the culture industry for broader popular sentiments, they serve as a crutch that allows yet another generation of historians to avoid the difficult work of explaining how spaceflight has influenced the material conditions of everyday life. For examples, see the essays in the culture and ideology sections of this volume.
act but is acted upon.\textsuperscript{5} In this context, conference presenters made strong assertions about the influence of space on society with very little, if any, evidence about changes in the lives of ordinary people to support those assertions.

By bringing ordinary people and social groups into our analysis, we can avoid reifying the concept of society and relegating masses of people to passive subjects of historical forces. To assess the role of spaceflight in society, we need to know the extent to which such activities altered work patterns, social practices, value systems, and how people relate to one another. We also need to know whether and how ordinary people resisted, reshaped, and adapted to changes brought on or supported in some way by space-related activities.

This paper suggests possibilities for examining the history of spaceflight through the lens of social history, focusing primarily on the relationship between the national space program and conceptions of status, race, and gender in the context of work, the community, and education. The most basic step for incorporating the concerns of social history into the history of spaceflight is to recognize as viable subjects for historical analysis all individuals and social groups involved in space endeavors regardless of their social standing.\textsuperscript{6} Adopting a social history perspective also requires dispensing with the notion of one-way impacts and instead understanding the space program as a site of human activity in which individuals, social networks, communities, and institutions are all participants in the process of change and in the attribution of meaning to historical changes. A third concept to borrow from social history is the notion that individual and group identities—how we see ourselves

\textsuperscript{5} Several schools of thought within the historical profession, from both social history and the history of technology, call into question the conceptual foundation of this conference. To historians of technology, for example, the conference theme may appear to have been conceived without consideration of longstanding discussions about technological determinism, the social shaping of technology, and the uneven benefits of new technologies. For a brief introduction to these streams of research, see Donald MacKenzie, \textit{Knowing Machines: Essays on Technical Change} (Cambridge, MA: MIT Press, 1996); Ruth Schwartz Cowan, \textit{More Work for Mother: The Ironies of Household Technology from the Open Hearth to the Microwave} (New York: Basic Books, 1983); Merritt Roe Smith and Leo Marx, eds., \textit{Does Technology Drive History? The Dilemma of Technological Determinism} (Cambridge, MA: MIT Press, 1994); and Wiebe E. Bijker, Thomas P. Hughes, and Trevor J. Pinch, eds., \textit{The Social Construction of Technological Systems: New Directions in the Sociology and History of Technology} (Cambridge, MA: MIT Press, 1987). Given that historical changes are typically the result of multiple forces, attempting to single out the contributions of spaceflight/NASA to specific changes (whether they are technological, social, political, or economic) may be an exercise in futility. A more coherent and balanced approach would be to reverse the search process—to start with specific changes and then attempt to identify contributing factors, focusing on the relative significance of spaceflight in comparison to the other factors.

and how others see us—are social creations that vary across time and place.7 With these basic concepts and the literature of social history as a foundation, this paper raises questions for further exploration regarding the role of the space program in creating the conditions for social and economic mobility and providing a forum for the negotiation of social norms and conceptions of race, gender, and status for the millions of Americans who benefited from NASA’s educational programs, lived in close proximity to NASA Centers, or worked directly for the Agency or one of its contractors over the past 50 years.

What Is Social History and How Might It Contribute to Space History?

Social history was a product of the 1960s, but not the 1960s the space community knows as the Apollo Era. Tensions over civil rights, gender relations, and an unpopular war in Vietnam inspired historians that entered the profession in the tumultuous decade to focus attention on groups that previously had been on the sidelines of American history, including women, the poor and working classes, and ethnic and racial minorities. Studies of migration, social movements, women, labor, and slavery dominated the field in these early years. As social history expanded, its practitioners borrowed methodologies from other academic disciplines. One group turned to quantitative methods to interpret changes in the material conditions of daily life, while others laid a foundation for cultural history by employing ethnographic techniques to explore the belief systems, rituals, language, and symbolic behavior of discrete communities. The field also broadened its topical scope and provided new insights on a variety of themes in American and world history, including immigration, social movements, demographic changes, education, leisure, ritual, social networks, sexuality, globalization, and consumerism.8

Social history has also influenced or bolstered similar trends in other history subdisciplines, including military history, urban history, the history of technology, Holocaust studies, and environmental history. Social history’s greatest contribution to the study of history has been its challenge to the assumption that formal politics, wars, and great men alone shape history and are the only subjects worthy of study. From the start, social history was based on the premise that everyday people are worthy subjects of analysis, not for sentimental reasons but because their actions, behaviors, ideas, and experiences contribute to historical change and offer a broader perspective on the past.

The willingness of social historians to experiment with a wide range of methodologies has complemented the field’s topical diversity. Over the years, social historians have borrowed freely from other academic disciplines, including anthropology, economics, sociology, psychology, philosophy, and literary studies. Grand narratives of societal change sit comfortably alongside quantitative studies of slavery’s effects and thick descriptions of local cultures on the shelves of social historians. While this interdisciplinarity has at times factionalized the field, it is indicative of a pluralist ethos that puts resolving questions about historical change over narrow methodological commitments.  

The two greatest weaknesses of social history have been the tendency of some writers to exaggerate the influence of the oppressed on historical change and the unwillingness of a large portion of the field to grapple with politics and political institutions. The tendency to portray minority groups as more influential in social and political change came in response to earlier histories that completely ignored the contributions of such social groups or portrayed them merely as victims. Although individual authors may still exhibit a bias one way or the other, the field as a whole has come to recognize the importance of capturing the contributions of all relevant social actors to political and social change. Despite a widely held assumption that social history is allergic to politics, furthermore, the earliest practitioners in the field never intended to abandon formal politics and political institutions completely. Some topics in social history have proven resistant to the incorporation of discussion of politics, but many of the most influential studies have explained changes in the lives of ordinary people within the context of larger political and socioeconomic trends. The best scholarship of the past 20 years, while not always identified explicitly as social history, has explored societal transformations through grand narratives that integrate politics, economics, demographics, and the experiences of ordinary people.

---

To reiterate, the best of social history is driven by the central concerns of historical practice: understanding causation, change, and continuity, and providing a basis for comparison of similarities and differences across cultures and societies. Social history is also malleable and expansive. Rather than a rigid commitment to a single methodology or theory, social history has been receptive to new approaches. Social history is also expansive in the sense that it attempts to understand the contributions of all relevant actors to the process of historical change, and its practitioners have always had a hunger for new topics (except those related to space history, of course). As with the New Aerospace History, furthermore, the best social history studies are situated within a larger historical and political context.

Rather than a side note in space history, the social history of NASA can be understood as a central element of U.S. history if we discuss it in the context of the federal government’s expanded role in science, education, and technological development in the twentieth century, and with reference to the individuals, communities, and social groups that defined their own existence and their ambitions in the shadow of the space program. The mundane aspects of NASA’s existence, including its relationship with employees, contractors, grantees, and the communities in which it has facilities, become more central to twentieth-century history when we recognize that they embody the tensions of a capitalist state attempting to retain its superiority over an anti-capitalist foe through technological advance. Discussing NASA as an arm of an expanded cold war state, rather than as it has defined itself—by its civilian spaceflight mission—allows us to deal more coherently with the Agency’s role in society.

With these ideas in mind, this essay will now suggest ways for incorporating the concerns of social history into the history of spaceflight in three contexts: the context of work at the NASA Centers and among space contractors; the context of NASA’s educational programs; and the context of the relationship between the Centers and the communities in which they are located.

**Work**

Although the topic of work has received a great deal of attention among social historians, studies that explore the labor process in the aerospace industry and the lives of aerospace workers are sparse. We have some sense of the perspectives of aerospace workers through Sylvia Fries’s study of Apollo Era engineers, and Howard McCurdy’s *Inside NASA* surveys NASA’s changing “confederation of cultures” throughout the decades. Some of the Center histories touch upon the social

---

lives of NASA workers and episodes of conflict between workers and managers, but our overall historical knowledge of the experiences of government and space industry workers remains shallow. No significant works in the field of space history explore the daily lives and work environment of the construction workers who built the Centers; the engineers, machinists, and production workers who created the technologies of exploration; the workers involved in assuring safe and continuous space operations; or the individuals at the lowest rungs of the employment ladder.

David Onkst’s dissertation, which focuses on the work lives of Grumman engineers, stands alone in dealing with questions of race, ethnicity, and workplace relations in the aerospace industry. It raises a few basic questions that deserve emphasis and should be explored in other settings. For example, what motivated workers involved in the space race? Were they motivated by national objectives, simple financial gain, personal pride, or a commitment to their peers? Onkst finds that the desire to do a good job and to attract positive recognition for themselves, their work unit, and their company, rather than patriotism or competition with the Soviet Union, served as the central motivation for Grumman aerospace engineers.

From this starting point, we can ask a whole new set of questions. How did the workplace culture and the approach of managers influence the motivations of workers and how they perceived their contributions to the space race? Were relations between workers and managers paternalistic, fraternal, or conflict-ridden? Did employees and managers share a common perspective on the quality of workplace conditions and the performance of work units? A few Center histories discuss labor conflict at NASA, but mostly in the context of the Apollo era. We have little sense of how management–employee relations have played out over time and among different segments of the workplace.

17. Benson and Faherty’s brief treatment of conflicts at Cape Canaveral in the 1950s and 1960s between the government and its employees, between craft workers and contractors, and between union and nonunion employees, suggests that a rich labor history of KSC workers remains to be told. Although President Kennedy took measures to prevent the rampant work stoppages that plagued government missile sites in the late 1950s and early 1960s from continuing in the 1960s and infecting the civilian space program, NASA’s relations with the construction trade unions remained contentious throughout the building of KSC. Charles D. Benson and William Barnaby Faherty, Moonport: A History of Apollo Launch Facilities and Operations (Washington, DC: NASA SP–4204, 1978), pp. 299–308. See also William Barnaby Faherty, Florida’s Space Coast: The Impact of NASA on the Sunshine State (Gainesville, FL: University Press of Florida, 2002).
Despite the weakness of unions in the space industry, they were not entirely absent. Grumman was somewhat unique in that it successfully prevented unionization through a combination of good compensation and paternalistic labor practices. What techniques and incentives did NASA and other space industry employers use to reduce the attractiveness of unionization? How did unionized corners of the space program differ from nonunionized corners in terms of the conditions of work and the attitudes of workers and managers?

Did workers throughout NASA and the space industry share the sentiments of one Grumman employee who described the company as a “classless work environment”? Benson and Faherty similarly described the atmosphere at the Kennedy Space Center (KSC) as devoid of “snobbishness.” What did “classless” mean in the high-tech workplace of the 1960s? Did differences exist across the Centers? Was the sense of classlessness greater at KSC than at the Jet Propulsion Lab (JPL), for example? My sense is that despite such claims, the notion of meritocracy was undergoing a transformation in the post–WWII period. Scientific and technical knowledge replaced pedigree and other forms of knowledge as markers of status. In this context, how did such meritocratic ideals shape how workers viewed themselves and others? Was a “classless environment” fostered, intentionally or unconsciously, to mute very real differences in power and status? If so, why was a putatively egalitarian rather than a strictly hierarchical atmosphere seemingly more appropriate for the aerospace workplace?

The contention that the technologies and organization of work structure both the workplace and broader social relations has its roots in nineteenth-century philosophy and remains influential in some corners of the historical profession today. In the context of NASA and the space industry, a softer version of the argument is worth considering—that certain production regimes privilege certain types of social

---

19. Ibid., p. 18.
20. Benson and Faherty, Moonport, p. 316.
relations and behaviors within the workplace. How did the format of the space complex—batch production, heavy design and testing elements, heavily reliance on networks of contractors and subcontractors, heavy government oversight, etc.—influence relationships between managers and workers? How did employees get around the imperfections and limitations of formalized management and reporting systems? What informal practices facilitated the completion of projects?

According to the historian of technology Eugene Ferguson, engineering education became based more on mathematical modeling in the 1950s and engineering schools stopped teaching design. Did trained engineers from the best universities need to go through a process of re-education to learn how to use slide rules when they entered the aerospace workplace, or did the new methods of the engineering schools come to dominate? To what extent did different educational experiences generate conflicts between older and newer generations of engineers? Sylvia Fries’s discussion of the reaction of Apollo engineers confirms both the dominance of computing over time and the concerns of older engineers with what might have been lost with the turn to computers. In terms of what was lost, Ferguson suggests that the Space Shuttle Challenger explosion and the problems the Agency faced with the Hubble space telescope were products of the engineering profession’s turn away from older

practices, such as visualization and “bottom-up design.” Although determining the veracity of such claims should be left to technical experts, historians can contribute to such debates by explaining how changes in techniques and knowledge have shaped relations across generations of NASA engineers.

How did conceptions of status and hierarchy relate to the opportunities for economic mobility that existed in the space complex? Social historians have long been interested in documenting both the reality and the ideology of economic mobility in the United States. To what extent did space work create a stepping-stone into the middle class? How important was economic mobility to workers in the space complex? For people who did move from lesser circumstances, what did their newfound status and wealth mean for them? What were the visible signs of their economic mobility? How did they relate to those who had come from better financial circumstances? Did the economically mobile retain ties to their friends and family who were not so fortunate? Finally, to what extent did conceptions of economic mobility, class, and social status change over time among space workers?

Social historians and labor historians have also studied the lives of workers outside of the workplace. Iconic images of risk-taking astronauts and “geeky”...
engineers notwithstanding, we know little about the social lives of the men and women who built and operated the equipment that made spaceflight possible. Few historians who have studied the NASA Centers have provided insight into the social lives of NASA contractors and employees, perhaps considering it a pedestrian topic or fearing intruding too much into the personal lives of individual workers. How did space workers deal with the stresses of work? Did managers and workers socialize? Was it common for engineers and scientists to intermingle? Did occupational categories factor into socializing? How important were bars or sports in social life? What role did formal and informal rituals play in work and social life? To what extent were sexually integrated or sexually segregated activities important to the social lives of workers? Were class, status, and gender differences muted or accentuated by such activities? How have formal NASA social events differed from informal gatherings among employees? What were the unarticulated rules of engaging in such activities? What were the implications of socializing for workplace camaraderie? Did such activities create a sense of common purposes and positive sentiments toward NASA? Did they serve as a safety valve? Did they help to homogenize social, political, or ethical values?

Historians have begun to explore questions about women and gender in the context of the space program. Yet, as Margaret Weitekamp notes in her excellent essay in the Critical Issues volume, much of this literature falls in the realm of compensatory history, adding the stories of women to the historical record rather than contextualizing their stories. Weitekamp’s analysis and proscriptions for dealing with gender stand on their own as essential reading for anyone interested in the topic. The point that the literature to date on women focuses almost entirely on

31. Bowles provides a few pages on the topic of social outlets at Plum Brook, which included playing music, formal social functions, dances, athletics, games, and practical jokes, some of which were loaded with gendered assumptions. Mark D. Bowles, Science in Flux: NASA’s Nuclear Program at Plum Brook Station, 1955–2005 (Washington, DC: NASA SP–4317, 2006), pp. 188–192. Benson and Faherty discuss the stresses of male engineers at KSC during the Moon race. Although KSC employees enjoyed opportunities for recreation along the Banana River and the waters of the Atlantic Ocean, work life was so consuming that the stresses of work commonly spilled over into the home. The children of space workers, according to a Titusville physician, had unusually high rates of ulcers. Benson and Faherty, Moonport, pp. 314–316.

women astronauts deserves emphasis. With the exception of a couple of studies that deal with women engineers, women workers and gender conceptions in the context of work have been ignored almost completely. Sylvia Fries's study of engineers during the Apollo era includes mention of women engineers, as does Sheryll Goecke Powers's short monograph on *Women in Flight Research at Dryden*. From these two works we get a sense of the hurdles that women scientists and engineers faced, as well as the nature of their work and changing opportunities for women within NASA over time.

M. G. Lord's memoir, *Astro Turf*, is exemplary in its treatment of historically situated gender constructions and could be applied to an analysis of masculinity at the Centers, as Weitekamp suggests. Following Lord's lead, historians could explore changes over time in gender conceptions, as well as differences across the Centers. Conceptions of gender, including topics such as manliness, domesticity, motherhood, and sexuality, deserve a great deal more discussion within the context of the workplace of the NASA Centers and the space industry. But we must not allow the discussion of gender and gender conceptions to remain isolated to those at the top of the work pyramid. Women in nonprofessional roles, including secretaries and support staff, deserve to be explored as legitimate historical subjects, as do the men at the lowest rungs of the work hierarchy, such as entry-level technicians and janitors.

The story of race is similar to that of gender in the sense that we have some sense of the experiences of black astronauts and a few of the histories of NASA Centers located in the south mention racial issues, primarily in the context of the civil rights movement and from a broad, top-down perspective. Dunar and Waring's history of Marshall Space Flight Center and Steven Moss's excellent master's thesis on NASA's implementation of federal civil rights policy in the South indicate that the

---

Agency as a whole took a strong stance on equal rights—promoting desegregation among contractors, universities, and local businesses near the centers—but NASA fell short of its goals in recruiting black engineers and skilled workers.\(^{38}\)

Without taking anything away from these studies, the literature to date falls short in several respects. First, it focuses exclusively on the South. The struggle for equality and improved work opportunities for African Americans was not confined to the South. Second, it tells little of the post-1960s story. The struggle to integrate the workplace did not end with the first Apollo lunar landing, nor did our habit of seeing ourselves and one another through a racial lens. Third, these studies leave the perspectives and actions of African American workers out of the story entirely. As David Onkst’s excellent dissertation chapter on race relations at Grumman on Long Island shows, African American workers and civil rights groups that supported them engaged in a wide variety of confrontational tactics to secure promotions and better-paying jobs. African Americans were not merely passive recipients of the actions of well-intentioned employers.\(^{39}\)

Onkst’s dissertation points to numerous opportunities for exploring race throughout NASA and among its contractors. In addition to further exploration of conditions in the South, historians might wish to look at changes in job opportunities and conceptions of race across all of the Centers and beyond the 1960s. If the history is not readily apparent, we might wish to search for instances of conflict in lawsuits, complaints from workers filed with the Equal Employment Opportunity Commission, and Congressional hearings. Onkst points out the startling figure of 125,000 cases in the EEOC’s case backlog in the 1970s.\(^{40}\)

In addition to cases of conflict, we need to gain a better sense of the less contentious ways in which minorities created advancement opportunities for themselves and in which the Agency aided their advancement. We know little about how formal groups (i.e., Hispanics in Government, Blacks in Government) and informal social networks have operated to provide career advancement opportunities, a sense of community, and have aided the quest for full workplace equality.

\(^{40}\) Ibid., p. 101.
LOCAL COMMUNITIES

Despite numerous studies of NASA Centers and some solid quantitative data on the local economic impact of NASA Centers, our knowledge of the role of the Centers, their employees, and NASA contractors in those communities remains shallow. Studies of the Centers focus primarily on activities within their gates. Some do not deal with the surrounding community at all, while others deal with it only in a cursory fashion, focusing primarily on quantifiable demographic and economic changes. One study discusses the NASA’s relationship with the local community from the perspective of the Agency—as a problem to be managed rather than a subject to be explored. Yet a few valiant attempts to explain the role of NASA Centers in generating and resolving local conflicts, and to characterize the contributions of NASA Centers to local communities, raise possibilities for writing the history of NASA from a local or multi-local perspective.

Despite the general lack of interest in understanding the local context of NASA Centers, at least two histories have explored specific conflicts between the NASA Centers and their communities. In Science in Flux, Mark Bowles skillfully examines the conflict between the government and local farmers over the World War II War Department’s forcible acquisition of the land that would eventually become Plum Brook. Bowles also remains sensitive to the viewpoints of members

41. See, for example, Annie Mary Hartsfield, Mary Alice Griffin, and Charles M. Grigg, NASA Impact on Brevard County (Tallahassee, FL: Florida State University, 1966); and Richard J. Keegan, “Economic and Social Impact of the National Space Program,” a report of the Stanford-Sloan Program, Graduate School of Business, Stanford University, 1971.

of the community surrounding Plum Brook who were concerned about living near a nuclear reactor in the 1960s and early 1970s. In *Power to Explore*, Dunar and Waring shed light on the relationship between the Marshall Space Flight Center and the city of Huntsville, Alabama, particularly in regard to civil rights, education, and the local economy. Despite their meticulous research and thoughtful presentation of what some might consider sensitive issues, Dunar and Waring provide only a top-level overview and leave readers with the sense that much more could be written on Marshall’s place in the rise of Huntsville as one of the most important small cities in the United States.46

Elizabeth Muenger’s brief description of the changing relationship between the Ames Research Center and Silicon Valley suggests the possibility of discussing change over time in the character of the relationship between NASA Centers and their communities rather than merely providing snapshots of controversies and collaboration or listing quantitative data on changing demographics and local economic conditions. Muenger explains the shift at Ames from isolation in relation to its surrounding community to stronger public relations after the formation of NASA. Under the National Advisory Committee for Aeronautics (NACA), Ames’s leader, Smith J. De France, discouraged employees from interacting in a formal capacity with members of the surrounding community and denied the broader public the privilege to attend triennial open houses. However, in the 1960s Ames became more active in promoting public education through teacher education and prize competitions, providing employment opportunities for local youth, and assisting local, small businesses.47

One theme that comes through in some of these studies is an insider/outside divide between employees at the Centers and the local community. Although based on limited evidence, the concept of insider and outsider deserves further consideration. In reality, we know very little about how well NASA employees integrated into the communities they inhabited.48 One would expect that they became regular members of the local community in every respect but, at least for the first waves of employees at newly built Centers after the formation of NASA, the question of initial contact is an important one. How did the entrance of highly educated outsiders into the community influence local social and political dynamics? How did local elites deal with sharing influence with newcomers, particularly newcomers who held meritocratic conceptions of status based on educational achievement? Did

newcomers integrate into existing social institutions, such as churches and social clubs, or did they create their own? Did local residents warmly accept the outsiders, or did conflict exist at the local political level or interpersonal level? What was the basis of such conflicts? Class? Culture? Racial or gender attitudes? How were such conflicts muted? To what extent did outsiders adopt local attitudes? To what extent did they simply grin and bear existing social and racial relations?

Or did the Centers have a significant influence on local perspectives? Did individuals who worked at the Centers, both outsiders and locals, learn anything from working in an environment that promoted equal opportunity that they carried with them to the local community? Did, for example, work at the Centers provide a context for reconfiguring conceptions of race and gender? Did the presence of a large federal employer mute racial antipathy? Did increased social standing in the workplace, for example, translate into increased social power outside of the workplace for African Americans and women? Did NASA employees draw upon their equal status within a federal institution to reshape local institutions and conceptions of race?

Works that hail the local economic impact of NASA Centers have attempted to put a positive spin on the negative consequences of NASA’s arrival in new locations. In his study of the Stennis Space Center, for example, Herring includes the perspectives of residents of Hancock County, Mississippi, who were forcibly removed from their properties to make way for the Center. Yet, he adopts the perspective of political leaders in framing the involuntary sacrifices of discontented residents as a necessary step in the path toward progress.49 It would be nice to know how the arrival of NASA facilities altered local economic patterns in each community and what the consequences were for native residents. Who, in particular, benefited? Existing elites? The poor? The middle classes? Did the Centers in any sense facilitate the opening up of local communities to broader national or international trade or social networks? Did the local economy become dependent on government largesse or did the NASA Centers facilitate the growth of self-sustaining companies that generated wealth from commercial ventures?50 To what extent did the children

---

49. Herring,  *Way Station to Space*, pp. 27–137. Faherty’s compact history on the impact of KSC on the Space Coast is well written, well conceived, and filled with excellent statistics and economic data, but it breezes too quickly over topics that would be of interest to social historians. Faherty,  *Florida’s Space Coast*.

of locals and newcomers, especially in previously isolated rural locations such as KSC and Stennis, follow similar life paths after graduating from high school? Did locals and outsiders come to share a common destiny and culture?

**Education**

NASA’s role in the education of millions of Americans is a topic barely examined except in the context of scientific and engineering programs.\(^1\) NASA has a long history of sponsoring education programs for elementary and high school teachers and students, providing grants to universities for research and training, and serving as a site of education through internships, temporary work positions, on-the-job training, and summer fellowships for university professors. A 1988 inventory of education programs listed 59 separate elementary and secondary education programs, 37 university programs, 30 minority outreach programs, 19 employment programs, and 17 public education programs—162 in total. While the combined programs reached millions of teachers and students, most programs supported a more limited number of individuals, often under 100, and a large number, at least at that time, were run out of the Field Centers.\(^2\) The implications of such activities for economic mobility are significant.

Who benefited from these programs? Can we identify any common patterns in their personal backgrounds? To what extent has NASA served as a conduit for social and economic mobility? In the course of such educational programs, what values unrelated to science and engineering have NASA conveyed? To what extent, for example, have educational programs succeeded in indoctrinating students toward the goals of the space program? How have such values conflicted with or reinforced other values and goals, such as religious values or requirements for diversity? To what extent, furthermore, have educators altered the space curriculum to accommodate competing social values?

One of the early directors of NASA’s Educational Programs Division claimed that many of the programs were established in response to external demands.\(^3\) This statement raises interesting questions about whether NASA was pulled into

\(^{1}\) One important exception is Virginia Dawson’s book on the Lewis Laboratory (now Glenn Research Center) in which she discusses the laboratory’s role as a locus of knowledge production and education. Through their research programs, most of the NASA Centers have served an educational function. Virginia P. Dawson, *Engines and Innovation: Lewis Laboratory and American Propulsion Technology* (Washington, DC: National Aeronautics and Space Administration, 1991), pp. 65–123.

supporting education for reasons apart from the Agency’s mission, or whether internal needs, or even presumed future needs, were the primary impetus for establishing educational programs. While the Space Act contains provisions for the widest practical dissemination of information possible, and NASA has been active in promoting education, to what extent has demand for knowledge, educational materials, and educational opportunities stimulated the Agency’s programs? Did the Agency ultimately benefit in cases in which the demand was largely without an identifiable NASA requirement or need? To what extent has the adoption of non-space-related responsibilities contributed to or detracted from the Agency’s ability to fulfill its central mission?

Women, minorities, and economically disadvantaged youth have been a focus of many of the educational programs. The only historian that I am aware of who has ventured into this territory is Amy Slaton, who studied the history of one university, Prairie View College in Texas, which received research and graduate training funding through NASA’s Historically Black Colleges and Universities program.54 Beyond the practical benefits of such programs, both for economic mobility for participants and workforce training and recruitment for NASA, what messages did such programs send to society at large regarding the federal commitment to equality? In what sense did such programs generate loyalty to the Agency? To what extent were such programs inspired by or tailored to local needs and socioeconomic patterns? How have external factors, such as the civil rights and women’s rights movements, impinged on both the focus and the content of NASA’s educational programs?

CONCLUSION

By whatever name—the Space Age, the Atomic Age, the Information Age—the period from achievement of the first self-sustained nuclear chain reaction on 2 December 1942 to at least the end of the cold war in 1989 represented a cohesive era in American history. Although many in the space community believe that the Apollo 11 landing on the Moon was the single most significant event of the century, we must not forget that the technologies of space exploration—not just the space race itself—were products of the cold war. The post-atomic military imperative to quickly and efficiently deliver nuclear weapons to precise locations spurred the federal government to invest massive sums of money in nuclear technology, rocketry, computers, and materials research. While the specific technological systems that made the Mercury, Gemini, and Apollo missions possible represented spectacular

engineering achievements, the likelihood that the space program would have existed at all without the discovery of the destructive potential of the atom or the military’s cold war space requirements is low. Just as significant portions of the technologies of exploration were built upon a foundation of cold war military technologies, so, too, NASA was built largely upon a foundation of military organizations.

Rather than isolated entities, the NASA Centers represented the civilian tip of a vast, interrelated complex of facilities and bases that served the cold war national interest. Social and cultural differences undoubtedly separated the people who worked from the communities that surrounded military bases, intelligence agencies, Department of Energy production and research facilities, and the NASA Centers, as well as the networks or electronics, nuclear, defense, research and development, and aerospace contractors that supported the government programs. We have almost no basis, however, upon which to make generalizations (let alone comparisons) about the social lives and culture of the communities that were most directly shaped by the vast expansion and geographical dispersion of U.S. government activities. Assumptions of cultural homogeneity should not prevent historians from studying military and space communities as unique cultural formations and considering whether the occupants of those communities represented or diverged from American cultural traditions and how they compare with other elements of American society.

Several generations from now, historians looking back at our time are likely to be just as interested in understanding how Americans of the Space/Atomic Age lived as they will be in understanding our technological achievements and changes in economic, political, and international dynamics. Robust social histories of the cold war and post–cold war may help to guard against the possibility that the cultural productions of the television and movie industry will substitute for actual knowledge of how Americans lived in this era.

As an astronomer and astronomy educator, I do not have any original historical research to report for this volume. Nevertheless, my hope is that this brief summary of some issues in the uneasy relationship between space science and education in the United States may be of use in getting historians and general readers interested, concerned, and perhaps even upset. A much more detailed overview of the state of astronomy education can be found on the World Wide Web.¹

The history and societal impact of space science education in the United States is difficult to sort out from the complexities of education in general. If it were an experiment, any scientist would throw up his hands in despair and say, “There are simply too many variables!” For example, what was more important in determining the attitudes of today’s U.S. adults about the space program:

- The various science education reform curricula in the 1960s that grew partly in response to Sputnik, or the growth of television as a pervasive, pernicious, and pseudo-educational medium?
- The Shuttle accidents and subsequent revelations, or the disintegration of the U.S. family due to the rise of divorce rates and single-parent families?
- The success of the Mars Exploration Rovers, or the consistently low salaries we have paid science teachers when compared to other professions requiring similar training?

These are very hard questions to answer.

To prepare this essay, I wrote to about two dozen experts in the field of space science education to see if they could help me find the most important parts of the literature on the impact of spaceflight on education. With one exception, they all wrote back quickly and courteously—to inform me that they knew of no such literature but that they were looking forward to our conference starting one.

Has the Space Age affected education in the United States? It is a romantic notion that it has. Everyone cites great anecdotes, memoirs, and TV shows such as *How William Shatner Changed the World*. But no one has been able to tease out the effect of the space program from the myriad other factors that affect our educational system. And, as educational researchers are fond of pointing out, “The plural of anecdote is not data!”

A recent paper in *Astronomy Education Review* reported that no research could be found that looked at teacher knowledge of astronomy across grade levels and multiple astronomy concepts. In the absence of relevant data, what I would therefore like to do, in the brief space I have, is to get the reader thinking just a bit about a few issues in the relationship between space science and education.

**A BRIEF HISTORY OF SPACE SCIENCE EDUCATION IN THE UNITED STATES**

Astronomy was a subject taught in U.S. high schools toward the end of the nineteenth century because it fit with the mental discipline model of curriculum. Like Latin and Greek, astronomy was supposed to be good training for student thinking, whether students needed it later in life or not. This approach soon began to unravel as the schools became less elite and more practical, and colleges demanded more practical knowledge from high school graduates.

Also, school curriculum under the mental discipline approach was hard, repetitive, and boring. In 1913, Helen Todd, whose job was to inspect factories, surveyed 500 children who labored there under difficult conditions. She asked if, economic circumstances permitting, they would not rather be back in school. Four hundred twelve out of 500 said no. They preferred sweatshops to what she called the “monotony, humiliation, and cruelty” of school.

In 1893, a Committee of Ten, set up by the National Education Association, was asked to report on a uniform curriculum for high schools that a variety of colleges could accept. (Before that, all colleges had set their own requirements and the situation was a mess, much like many of the local K–12 standards we have across the United States today.) The committee, chaired by Harvard President Charles Eliot, had many suggestions and many critics. But for us, one consequence was that they defined the main science topics as biology, chemistry, and physics—and

---

4. Ibid., p. 6.
astronomy only as an elective. It soon began to slip into the noise of the demands on American curriculum, and today, few schools teach a separate astronomy class (and then only as an elective).\(^5\)

It is true, as those who follow the politics of the space race know, that the National Defense Education Act of 1958 (the reaction to Sputnik) increased the amount of science and math being taught and led to some interesting curriculum studies and reform, especially in elite schools.\(^6\) But it is not clear that things in science education got better in the long run. Other factors besides curriculum play an ever-increasing role in the education of our children. Teacher training or lack of it, latch-key kids, peer and media pressure against seeming smart (think of films such as *Dumb and Dumber*, MTV—all have combined to “beat us” far better than the Russians ever could have.

What space science students do get in our schools today is mostly found in general science, Earth science, and physical science classes in middle school and high school. Numbers are hard to come by, but many factors are contributing to a decline in the amount of space science being taught. Let’s consider just three of them.

First is “the less is more” movement among science educators and those who train them. This movement, which says we should teach fewer topics in science but in greater depth and with more hands-on activities, is generally a positive development in getting students to learn what real science is about. But there are already very few hours devoted to science in the curriculum. Generally, when time is short, basic biology, chemistry, and physics take precedence.

Next we have the lack of trained teachers to teach science. During the 1999–2000 school year, only 55 percent of high school students received physical science instruction (chemistry, Earth science, and physics) from a teacher with a major or minor in physical sciences. At the middle school level, only 18 percent of students received physical science instruction from a teacher with a major or minor in physical sciences. Nearly 50 percent of middle school students received physical science instruction from a teacher without a major or minor in any science or science education field.\(^7\)

---

Finally, consider the effects of the No Child Left Behind Act (and the general tendency in the United States toward simple-minded, multiple-choice testing as a measure of teaching and learning). Right now, schools are required to test all students in math and English, but by the 2007–2008 school year, states must test all students in science three times: in grades 3–5, 6–9, and 10–12.

The good news is that districts that had shifted emphasis away from science in the last few years because the testing for English and math was first and science was still in the future, will now have to start putting more emphasis again on science, since science testing is going to be a reality! The bad news is that science exams will not be used to determine whether schools are making “adequate yearly progress,” so the pressure from those exams is not as great. Still, science test results will have to be publicly announced (to the parents), so they will be part of how parents and the public judge the schools.

But the far greater issue will be that each state will be allowed to set its own standards and to decide just what kind of science tests to offer. And, make no mistake, once the tests are set up, science teachers will teach to the tests! Anything not being fully tested will be much less likely to be taught. In my home state of California, to take an example, far more high school students take biology than physics. As you can imagine, there is pressure to make the grade 10–12 tests about biology only. If that is so, it will tremendously accelerate the trend to take biology over other sciences.

How will space science do in all this? Unless its teaching and testing are mandated by the states, what teachers will have time to teach astronomy with the short school days and short school years and all the pressure to do well on the standard tests that are increasingly the hallmarks of the U.S. educational system?

How many of you know how much space science is in your state standards? How many of you have participated in the fashioning and review of those standards? How many of you have talked with a local science teacher and tried to encourage increased teaching of space science? Yet if we, who have a deep interest in space science, are not engaged in this process, how can we expect others to carry the torch for us?

Science Education and Science Literacy

Lest you think that space science education is being uniquely singled out for failure, I note that things are not great throughout the arena of science education. In 2000, the National Assessment of Educational Progress indicated that in the United States only 29 percent of 4th graders, 32 percent of 8th graders, and a depressing 18 percent of 12th graders performed at or above the level termed proficient in science for their grade. Roughly half of all freshmen entering California state colleges

---

8. Ibid., Chapter 1.
cannot understand English or math at the college level and need remedial courses.⁹ It is also an interesting statistic that in 1956, the year before Sputnik, there were twice as many B.A.’s in physics in the United States than there were in 2004.¹⁰

The results of the lack of good science education in this country is that adult Americans know very little about science. Jon Miller of Northwestern University, the foremost science pollster in the United States, has come to the conclusion that fewer than 20 percent of adult Americans know enough science for minimal civic literacy. For example, 50 percent of adult Americans believe that humans lived at the same time as dinosaurs. Only 22 percent of adults in the United States can correctly define a molecule.¹¹

At the same time that American science literacy is declining, the U.S. Department of Labor reports that in the next decade jobs requiring science, engineering, or technical training will increase by 51 percent—four times higher than general job growth. Where will all the trained people to hold those jobs come from? Clearly, the reports warning that the competitiveness of our country may be undercut by the lack of adequate education in science and engineering are worthy of far greater political attention than they have so far received.¹²

Now that I have thoroughly depressed you in general, let me at least mention one comparatively positive trend. Others in these conference proceedings are focusing their papers mostly on the programs involving human spaceflight. But these are only one part of how NASA has transformed public perception; the other part is the array of robotic missions and telescopes whose images are now part of the visual and verbal vocabulary of our times.

Even the lowest-level science textbooks are full of the images these missions have returned to us. Just think about the visual impact and drama of these:

- The Hubble space telescope views of star birth in the great clouds of cosmic raw material, black holes at the centers of galaxies, and the depths of galactic space.
- The Voyager mission images of Jupiter, Saturn, and their moons.
- The Galileo spacecraft’s first close-up views of asteroids (and an asteroid with a moon).
- The continuing pictures from Spirit and Opportunity, the intrepid little Mars Exploration Rovers.

⁹. This statistic has been cited by California newspaper reports for years. It is confirmed by the information provided by the California State University system, such as http://www.calstate.edu/pa/news/2004/proficiency.shtml (accessed 27 March 2007).

Planetary science, as Carl Sagan stressed, has in one lifetime converted the planets from dots in the sky to worlds with tourist attractions. And Hubble images adorn musical CD covers, advertising, popular books and magazines, and even toys.\(^\text{13}\)

One benefit of all this is that people seem to have an almost proprietary interest in the solar system these days. Witness the public and media uproar that followed the perceived downgrading of Pluto’s planetary status.\(^\text{14}\) NASA officials have also told me that the millions of hits on the Mars Rover Web sites and images have far exceeded everyone’s expectations. In this way, the vision of robotic spaceflight has succeeded beyond our wildest dreams. It is part of the cultural landscape—video games, movies, television, comic books, and amusement parks all take a public familiarity with space probes and the planets for granted.

A marvelous example of this was the television program *The West Wing*, created by Aaron Sorkin. Although the show portrayed mostly Washington politics and the lives of those working in the White House, it was also one of the best “stealth space science education” vehicles I have ever seen. (And, not coincidentally, it was one of the few shows on television that made being smart an object of pride rather than ridicule.) Throughout the series, Sorkin introduced NASA missions and astronomical ideas. (Even the program I directed at the Astronomical Society of the Pacific, Project ASTRO, was mentioned once.) And the president of the United States was shown as loving space science and robotic planetary exploration and eager to show off about it to school kids.\(^\text{15}\)

We need to enlist other friends in the media and public relations world to do more stealth science—science that becomes part of our popular culture and can insinuate itself into the public awareness. We should be putting stealth science into our TV shows, malls, parks, airport waiting areas, fast food places, and anywhere else we can.

**The Mixed Blessing of Astronomical Pseudoscience**

One negative result of this widespread but suffused public interest in space travel and astronomical ideas is that some of our cultural need for the supernatural has recently become translated into space-related terms. Whereas people in past

\(^{14}\) See, for example, Andrew Fraknoi, “Teaching What a Planet Is: A Roundtable on the Educational Implications of the New Definition of a Planet,” Astronomy Education Review 5, no. 2 (2006), available online at [http://aer.noao.edu/cgi-bin/article.pl?id=207](http://aer.noao.edu/cgi-bin/article.pl?id=207) (accessed 27 March 2007). References at the end of this roundtable discussion can lead you further into other responses.

centuries saw supernatural visions in terms of guardian angels or leprechauns or haunted houses, today these same feelings are expressed through UFO and alien abduction experiences. A 2001 Gallup poll, for example, revealed that fully one-third of adult Americans believe that extraterrestrials are visiting Earth. And 31 percent accept the tenets of astrology, that the position of the Sun, Moon, and planets at the time of our birth can affect our personality and destiny.

In a way, those of us concerned with education should be grateful for the growth of tabloid-level interest in alien life-forms or completely misinterpreted “faces” on Mars. Although some students or adults may become interested in space science through such nonsense, they can sometimes go on to learn or read about the real world of space and astronomy once their interest is piqued. Still, without better information about the scientific method in our schools, our media, and in our public consciousness, too few people have the tools to go beyond a fascination with pseudoscience to the real science that would await them.

Still more disturbing, a 2004 Gallup poll said that 45 percent of Americans believe that God created humans in their present form at some time in the last 10,000 years. When asked about the origin of humanity and being given several choices, only 13 percent of Americans chose an answer that did not include something about God’s role. A December 2004 *Newsweek* poll asked whether respondents favored teaching creation science in addition to evolution: 60 percent favored it, 12 percent were undecided, and only 28 percent were opposed. For many people, this seems to be only fair, in a loose, democratic sort of sense. Many of these people are the ones who have a problem understanding the scientific method and ways of deciding on evidence in science.

18. This is the approach of Phil Plait, who uses these crackpot ideas to teach about science. See Philip C. Plait, *Bad Astronomy: Misconceptions and Misuses Revealed, from Astrology to the Moon Landing “Hoax”* (Englewood Cliffs, NJ: Wiley, 2002).

This ambiguity about (or ignorance of) the scientific method spills over into public views of the teaching of astronomy as well. The legislatures of a number of states (including Kansas) have begun to pass laws, at the behest of fundamentalist religious groups, to include anything that contradicts a young Earth and young universe in the subjects that should be taught “only as a theory” or taught with “alternative theories” or de-emphasized. This includes radioactive dating and Big Bang cosmology—ideas essential to understanding the longevity and formation of the universe. (The key issue is that the time scales of our modern understanding are too long to satisfy those who seek to promulgate a very literal interpretation of the Bible as science.)

In response, scientists have begun to speak up and write about these issues. The Education Board of the American Astronomical Society has produced a booklet and Web site called *An Ancient Universe* to help teachers and school board members understand how we know that the natural world is old. Other members of the space science community are now writing and talking more about the need to answer such claims, particularly to help beleaguered teachers in those states where the fundamentalist pressure is the greatest.

We might note, as one example of why science educators are concerned, that religious radio stations now number almost 2,000—all but a few controlled by evangelical Christian organizations. They outnumber every other radio format except for country music and news talk. In general, the political and media clout of evangelical Christian organizations is growing, while the amount of time devoted to serious science on the radio and many TV networks is shrinking. There are two syndicated short radio features about space science, *StarDate* and *Earth & Sky*, but their brief spots are hardly enough to overcome the relentless radio proselytizing of the religious right.

**Case Study: A NASA Education and Outreach “Ecosystem”**

I hope it is clear even from such a brief introduction that those interested in the expansion (or even continuation) of astronomy and space science education in the United States have a huge task before them. Most teachers, especially at the elementary level, have little or no background in the field and are unlikely to teach

---

The Good, the Bad, and the Ugly

much of it without requirements to do so, or active training or assistance. Even many upper-level teachers see it only as possible appetizer for the main dish of the “regular” sciences.

Since there are only on the order of about 10,000 space scientists in the country, it is hard for a community that small to have a major effect. What is needed is either a larger community of interpreters to help us, or a “leveraged” effect where the work we do can translate into a cascade of influence. The first thrust is being pursued by the Astronomical Society of the Pacific, among others. For example, Project ASTRO is a program that trains amateur as well as professional astronomers (and college students) to partner with teachers in grades 4–9 to bring effective, hands-on astronomy activities into classrooms. It is presently operating in 13 regional sites around the country.24

The second thrust is far more difficult and requires the kinds of effort that only a major government initiative might have the resources to undertake. In the brief space I have, I would like to conclude with one specific case study where NASA’s educational efforts have had a disproportionately important and salutary effect.

Today, about $40 million per year is flowing from the NASA’s division formerly known as the Office of Space Science (now part of the oddly named Science Mission Directorate) to a whole range of educational and public outreach (EPO) programs. It has been, over the last few years, the largest investment space science EPO in the history of our country.25 It’s a good story about a little-known effect of spaceflight on education that I hope will be written up in more detail by future historians.

In the early 1990s Congress began to ask the science enterprise in the United States to document how it was benefiting the nation and it asked the science funding agencies, such as the National Science Foundation and NASA, to be more explicit in requiring such justification. At the same time, NASA’s Office of Space Science also had some concerns about how effectively NASA’s Office of Education was conveying the excitement of fundamental science, as opposed to piloted spaceflight done for political and other reasons (that sometimes wound up having little connection to science).

So the Office of Space Science hired (in a quiet way) a series of dynamic leaders in the field of education to create its own EPO program—focused much more strongly on space science and not on what astronauts ate for lunch. Another aim

of the program was to involve space scientists in an active and leveraged way in the
education effort. Eventually, the program would find its influence by requiring each
of its instruments (missions) and research programs to devote 1 percent to 2 percent
of its budget to EPO. When larger programs, such as the Hubble space telescope, were
involved, those small percentages generated a considerable amount of money.

Dr. Cheri Morrow began to organize this community in smart ways and to
write material to facilitate better EPO programs, but the real progress came with the
appointment of Dr. Jeffrey Rosendhal, a veteran Washington and NASA hand, who
in 1993 took this effort in a novel direction. After getting advice from education
experts around the country, Rosendhal set up what he called an “ecosystem” for
EPO. Rather than each scientist, each institution, and each mission pursuing EPO
on its own, the ecosystem would coordinate and amplify the individual efforts so
that the overall effect could be greater than the sum of its component parts.26 There
were two distinct parts to the organizing ecosystem:

• A series of topical forums to coordinate EPO activities among like missions (for
example, among those exploring the solar system), and

• A set of regional brokers/facilitators to link missions and scientists to the real
world of education.

The brokers were supposed to act like old-fashioned marriage brokers did—
setting up relationships between the scientists and professional staff doing a NASA
mission and local school systems, museums, educational publishers, nonprofit societies,
etc. Although not all parts of this system worked right away, the coordination these
strategically placed elements provided did help take the NASA space science EPO
program to a new level, going way beyond the usual bookmarks, key chains, and
pretty lithographs that were the hallmark of earlier mission outreach.27

Rosendhal and his staff also set up a series of small educational start-up grants
(the IDEAS program) and a way for scientists who already had research grants from
the Office of Space Science to request an EPO supplemental grant for some kind
of educational project involving scientists or graduate students.

When all these vehicles for doing education and outreach were added together,
by the year 2003, 400,000 people around the country had participated in 5,000
educational programs or events; 6 million had visited some Internet site sponsored
under the program; and a whole host of curriculum modules and learning materials
had been created and infused into the educational system.

26. See, for example, “Partners in Education,” http://spacescience.nasa.gov/admin/pubs/edu/eduov.htm; and
imp_plan.htm (both accessed 27 March 2007).

27. The system’s Web site can be found at http://science.hq.nasa.gov/research/ecosystem.htm (accessed 27
March 2007).
As someone who served on the review committee that was set up to see how well the system was doing after the first few years, I can personally attest to the fact that the leaders were open to criticism, able to make changes and course corrections, and had the best interests of education in mind.\textsuperscript{28} I was also impressed by the fact that the system worked not only by itself, as NASA education has often tended to do, but was willing to partner with respected institutions and programs in the outside world.

An excellent example of this is that the program, instead of merely inventing more curriculum modules of its own, worked with such curriculum developers as the GEMS program at the Lawrence Hall of Science. And instead of developing curricula focused solely on NASA missions, the investment was in modules that would increase students’ general background in space science (including elementary ideas that are often taught incorrectly in the schools.)

\textbf{The Growth of the Community of EPO Professionals}

Now don’t get me wrong. NASA’s Office of Space Science was not alone in making investments in and becoming more sophisticated in its understanding of the real worlds of education and outreach. The National Science Foundation, the national observatories, the American Astronomical Society, and the Astronomical Society of the Pacific were also increasing their involvement in these areas around the same time. Universities, research labs, and observatories also found it to their political advantage to become more involved in public education. But there is no question that the NASA investment and involvement were the most significant, both in terms of the size of the budget and the sophistication of the approach.

As a result, there was suddenly a critical mass of education and outreach workers in the United States, all doing work outside the traditional classroom—and a new profession may have been born.\textsuperscript{29} Think about how a job category becomes a “profession” in this country, whether we are thinking of lawyers (who have done a great job with this), podiatrists, teachers, or NASA historians. Some of the factors that make a profession include professional organizations, journals and newsletters, awards, and a shared literature. Soon, most professions develop a mode of certification—a way of training candidates for the profession which guarantees that certain shared goals and standards will be observed (and that those who do not share those goals and standards will be excluded). Such modes of certification can include undergraduate or graduate degree programs, apprenticeships, examinations,

\textsuperscript{28} The review can be found on the Web at \url{http://newfrontiers.larc.nasa.gov/PDF_FILES/NASA_OSS_EPO_TF_Report_FINAL.pdf} (accessed 27 March 2007).

certifying boards, professional development programs, and (of course) fancy certificates printed on parchment to put on your wall.

The new profession is just beginning to make its way through this list. There is now a journal, called *Astronomy Education Review*;30 there is an annual conference held by the Astronomical Society of the Pacific; and several awards (including the American Astronomical Society Education Prize, the Klumpke–Robert Prize, the Las Cumbres Outreach Award, and a new education prize from the Astronomical League) are now given specifically for education and outreach work. At least one group, at the Center for Educational Technology in Wheeling, West Virginia, is beginning to think about a master’s degree program in EPO work. Several of these profession-building steps are happening with NASA support but there is still a way to go before the community of such workers becomes a profession.

For example, there are still no agreed upon standards for entering the profession, so that some people come with extensive background in science and/or education whereas others are trained on the job. Many scientists dabble in the field without feeling the responsibility to get to know the literature of astronomy education, in the way that they would if they dabbled in a field of space science research. To some degree the new EPO profession is still what physics education researcher Joe Redish calls “a community of weakly interacting individuals.” Nevertheless, the seeds of a new profession seem to have been planted and NASA’s efforts have been a major cause of why some of those seeds may be starting to bloom.

Although some disturbing recent changes in the NASA funding picture may profoundly impact the support this fledgling profession that NASA has had such a strong part in creating, I suspect the sense of community and the movement toward professionalization could well continue if the funding is diminished.31

**Conclusion**

So what can we conclude about the impact of the space program on education in the United States from this brief review? There were certainly strong influences on small subgroups, which are recorded mostly anecdotally and are worthy of more serious study. There are cases, such as the NASA Office of Space Science ecosystem, where a small, leveraged infusion of funds can make a significant difference in the

---

30. The journal is available only online at [http://aer.noao.edu](http://aer.noao.edu) (accessed 27 March 2007).

31. The new Administration at NASA is indicating that they do not believe that education should be a primary mission of the Agency. They are also being quite honest in letting Congress and the public know that they simply cannot accomplish all the goals set for NASA with their present funding. By giving higher priority to piloted spaceflight, replacing the Shuttle, continuing the International Space Station, and other (often politically motivated) programs, they are consigning science and science education to lower priorities. Many commentators are predicting this will soon translate into lower funding and thus to less money being available for the EPO system.
effectiveness of EPO programs. But changing the educational system in the United States as whole is a monumental undertaking, one completely beyond the resources of a small government agency, a single industry, and a group of enthusiasts. Whether space science can play a pivotal role (or even a supporting role) in bringing such a change about remains to be seen.

The educational system in our country reflects and enforces our best and worst values. Pockets of entrepreneurial effectiveness can be found among vast bureaucratic morasses of lazy and lackluster learning and teaching. Having an influence on this system will require a concentrated national effort whose expense and difficulty might well put the Apollo program to shame.
Race and gender are almost invisible aspects of the early Space Age. The civil rights movement, the women’s movement, and early spaceflight occurred simultaneously, but they are normally analyzed as if they occurred in separate universes. Realities were different; there was a social history of the Space Age. Exclusions of women and racial minorities from key portions of America’s civilian space effort have had major effects on the political credibility of spaceflight.

Recent books on how the U.S. Astronaut Corps stayed closed to women in the late 1950s and early 1960s, and about how it opened to women of all races and minority men after 1978, tell part of this story. But the political struggles within and around NASA that made such openings a political necessity remain unknown. This essay addresses the fight to make America’s space program—like America itself—more diverse and inclusive.

NASA’s Troubles

Late in 1973, NASA was an agency in budgetary, policy, and staffing trouble. Efforts to gain public or political support for a human mission to Mars had failed resoundingly in 1969 and 1970. As the Apollo lunar program ended in December 1972, NASA was losing no less than one-third of its civil service workforce. Between 1965 and 1975, the Agency also lost half of its budget, in purchasing power terms. In national opinion polls, only foreign aid had less support than space exploration; even welfare spending fared better.¹

A major reason for NASA’s difficulties was that the society around it was changing. An era of external cold war military and diplomatic concerns was giving way to an era dominated by domestic social and economic issues. Chief among these were the fast-paced rise of environmentalism, the women’s movement, and the African American civil rights movement. Every recent poll, NASA’s George M. Low noted privately as early as July 1970, showed that space and national defense had little appeal. American society was opening up to major new political constituencies in a fashion not seen in almost 40 years.²

By October of 1973, Washington, DC, and the nation beyond it were also in the midst of the wrenching Constitutional crisis called Watergate. In June, former White House Counsel John W. Dean implicated Republican President Richard M. Nixon in a conspiracy to obstruct justice regarding political spying and sabotage carried out against his Democratic and other enemies. In July, investigators for a special prosecutor’s office created by Congress uncovered the existence of a White House taping system that could confirm or disprove Dean’s charges. Political stonewalling and judicial guerilla warfare then commenced in earnest after Nixon refused to provide access to unsanitized versions of the official records of this presidency.³

Finally, accumulated pressures caused multiple political faults. First, on 10 October 1973, Vice President Spiro T. Agnew resigned over a bribery scandal. As one of Nixon’s key partisan warriors against “radical liberals” surrendered, Nixon himself counterattacked. From 15 to 19 October, Nixon demanded that Special Prosecutor Archibald M. Cox cease requiring unedited White House tapes. After Cox refused, Nixon fired him in the “Saturday Night Massacre” of the 20th of October. In a pre–Internet world, 250,000 to 300,000 telegrams then cascaded into Washington, demanding Nixon’s impeachment for high political crimes and misdeeds. The mood in Congress was grim. The New York Times and major regional papers editorialized that Nixon should resign, and The Washington Post called for impeachment. Time magazine, long a Nixon supporter, sadly noted he had “irredeemably lost his moral authority, the confidence of most of the country, and therefore his ability to govern effectively.”⁴

Until precisely this point, NASA had avoided any connection with the dangerous and polarizing politics of Watergate. But, on the 11th of October, one day after Agnew’s resignation and as the battle between Nixon and Congress, the courts, and the special prosecutor’s office peaked, NASA performed a “Nixonesque purge”

---

of its own. In doing so, it threw itself into the firestorms of the final year of Nixon’s plagued presidency. Ironically, it also began a process of political protest and oversight that opened up the U.S. civilian space program to women and to racial minorities.5

THE “NIXONESQUE PURGE”

The occupational desegregation process began when NASA fired Mrs. Ruth Bates Harris, the highest-ranking woman in the Agency, for submitting a private report to NASA Administrator James Fletcher stating that NASA’s belated equal opportunity program was “a near total failure.” NASA still employed fewer racial minorities and women than any other agency in the federal government. What women it did hire were almost all clustered in dead-end clerical jobs, and still nothing had been done to open the Astronaut Corps to anyone but white men. “Without denying the validity of the materials in the report, the agency fired its principal author,” noted an indignant Washington Post editorial of November 24. Despite Fletcher’s statements that NASA understood and was dealing with civil rights in employment problems for previously excluded or discriminated-against groups in its largely Southern installations, The Washington Post (located in a city which had grown from half to two-thirds African American in the 1960s) was not impressed. “Institutionalized racism and sexism” existed throughout NASA, it concluded. “[N]either simple pieties nor eloquent declarations of principle” would change that fact. The Washington Post illustrated this by quoting a NASA Headquarters spokesman who “made a large point of the fact that the agency official who [most immediately] recommended Harris’s dismissal was himself black”—“physically blacker than Mrs. Harris,” he said.6

NASA was now in major political trouble with no strong president to protect it. Its rocky ride through the new politics of America in the 1970s was about to get rockier still. How had it all begun? Basically, an elite agency began coming to social understandings late; when it did, it proceeded to address them in a half-hearted and ambivalent fashion. Not feeling it had much to learn, it denied that problems—or solutions—existed.7

7. One way to understand how visible and important was the case started by the Ruth Bates Harris firing is to see how many stories exist about her, in whole or part, in the online index to The Washington Post. From 1965 to 1985, this number totals 222. See http://pqasb.parchiver.com/washingtonpost/search.html/?nav=left (accessed 18 January 2005).
NASA ignored social issues such as affirmative action (compensatory activity for those previously excluded from occupations or training by rules or custom) for as long as it could. It was not alone. *The New York Times*, *Newsweek*, and ABC News all discriminated against and excluded women from many jobs, just as television news stations generally refused to hire female reporters of any hue throughout the early 1970s. 1968 through 1971 nevertheless marked a watershed in enforcement of civil rights in employment laws for women and racial minorities in both the private and public sectors.

Further, in 1971 the Supreme Court, in the *Griggs v. Duke Power Company* case, enunciated a clear compensatory action and preferential treatment argument. A previously segregated Southern utility was using competency tests that had a “disparate impact” on minority groups. The court ruled it could not do so unless the tests had a very clear relationship to advertised jobs. “Business necessity” claims for minimum educational attainments or literacy levels were not enough. No intent to discriminate against individual applicants needed to be proved if a pattern of group exclusion was demonstrated. The burden of legal proof, bluntly, was shifted from the historically excluded worker to the employer. Given the very long history of occupational exclusions and low funding for segregated African American schools in Southern states, the utility had to make up for the effects of past discrimination in the present and the future.8

Most NASA installations were located in the apartheid American South. The aerospace sector of the economy was also no stranger to job discrimination. A Wharton School report of 1966 noted that African Americans were simply excluded from the aviation industry until World War II and very rarely achieved higher occupational standing thereafter. Just as there were no African American aviators until the wartime Tuskegee Airmen proved to segregationists that African Americans were mentally capable of flight, pre-1941 anti–African American policies were not disguised in corporations. African Americans pushed brooms; whites built airplanes. In the Apollo era of the 1960s, one-third of 1 percent of managers and seven-tenths of 1 percent of professionals in the 60 percent of firms supplying data were African American. The largest wartime and cold war changes, most pushed by unions such as the United Auto Workers, were in semi- and unskilled labor ranks, where 8 percent and 14 percent of workers, respectively, were African American. Office and clerical staff (2 percent) and skilled workers (3 percent) lagged badly, compared with the 20 percent of broom-pushers who were African American in 1966. Aerospace executives generally stated that “direct experience” was essential to success in their industry, while making few, if any, efforts to upgrade such minorities or women as they had already hired.9

NASA reflected the mindsets and occupational patterns of the sector of the economy from which most of its engineers, scientists, and technical managers came. Despite a brief “Rosie the Riveter” interlude during World War II, (white) women disappeared from aerospace—except as clerks and typists—postwar. Women of any race were also not normally admitted to technical schools or to undergraduate or graduate training in engineering and the physical sciences until the late 1960s without intense personal effort. Female engineering Ph.D.’s, accordingly, were less than 4 percent of the total even 25 years after Sputnik. Levels of 10 percent weren’t reached until 1990. In that latter year, by comparison, 40 percent of Ph.D.’s in biology and 50 percent in the social sciences and humanities were women. African Americans, meanwhile, still only earned 2 percent of all doctorates in all fields of science and engineering in the 1990s, and only 5 percent of the bachelor’s degrees in aerospace, electrical, and mechanical engineering specialties of prime interest to NASA in 2002, while Native Americans and Hispanics were as low and lower.10

The effects of the lags in both the aerospace sector and in physical sciences and engineering education could be seen in NASA’s approach to race and gender issues. Until September 1971 (in the wake of Griggs), NASA had no systematic civil rights element in its employment program at all, even though three-quarters of its facilities were located in Southern states, including Virginia, Alabama, Texas, Louisiana, Florida, and Mississippi. Instead, NASA’s director of personnel in Washington carried out tasks “on a part-time basis.” The labs where most of NASA’s people worked, meanwhile, were generally devoid of any organizational structure, lines of responsibility, or policy guidelines regarding affirmative action.11

The ad hoc approach, however, was no longer enough because, also in 1971, groups such as the Women’s Equity Action League, the NAACP Legal Defense Fund, and the National Organization of Women banded together to bring successful suits against for-profit and nonprofit organizations accepting federal money in any form. Suddenly and decisively, elite meritocracies such as Harvard University and

the University of Michigan were in the same legal position as any of the 10 major integrated aerospace contractors at that time. By 1972, Congress further extended the scope of affirmative action when it ordered all executive-branch agencies, including NASA, to obey the same civil rights employment rules now mandated on private firms and state governments.12

A “Harlem Princess” Comes to NASA

Accordingly, NASA’s newly installed Administrator James Fletcher started off his tenure as the fourth leader of the U.S. civilian space program with bold moves on the civil rights front. On 24 August 1971, several months after he assumed office, a press release signed by Fletcher announced that a 52-year-old African American woman, Ruth Bates Harris, would become NASA Headquarters’s new Director of Equal Opportunity. Harris would “provide direction” to all civil rights in employment programs for all the “approximately 29,000 NASA Civil Service employees.” This would include the top managers at all of NASA’s far-flung labs. She would also oversee “contract compliance”: the hiring of women and minorities by the many private firms providing products and services to NASA facilities. The new head of an agency whose “social center of gravity was exceedingly conservative” had just acted decisively.13

Ruth Bates Harris, who died in 2004, “Courtesy of University of Kansas Libraries”

The woman Fletcher hired was a self-described “Harlem Princess” whose first marriage had been to a Tuskegee Airman. An honors graduate of Florida A&M University, she had gone on to earn an M.B.A. with a specialization in personnel and industrial relations from New York University. What Fletcher called her “distinguished career in human relations” included service as the executive director of the District of Columbia Commission in Human Relations, a civil rights oversight and implementation group. Her nine-year tenure at the DC Commission began with a successful push to get *The Washington Post* to stop carrying racially restricted housing ads, and moved on to an increasing variety of housing, community–police relations, and other work. Through several “long hot summers” of racial discontent in the late 1960s, Harris was among those who exercised front-line leadership in restoring peace and stopping (or avoiding) riots. Because inhabitants of the nation’s capital had only gotten the right to vote for local government in 1967, Harris not only became a de facto affirmative action officer for city government in a majority-African American metropolis, she also learned to work well with the Congress and senators of all political persuasions who were the overseers of DC government. As the Congressional Black Caucus was formed (in 1969), as *Ms. Magazine* first began publishing (in 1971), and as the Equal Rights Amendment first passed both houses of Congress and Congresswoman Shirley Chisolm became the first woman—and first African American—to seek the nomination of a major party for the presidency (in 1972), Harris worked hard to understand and guide quiet revolutions in race and gender relations. “I’m never just talking about people being nice to each other. I’m talking about changing the system,” she told a civil rights oral history interviewer for Howard University in 1971. “We ought to have one big coalition...[of African Americans and]...all our minorities [with which] we could change anything in this system.”

Ruth Bates Harris was a bridge-builder, not a wild-eyed or other radical. In 1969, for example, she left the DC Commission to become the human relations director for the public school system of Montgomery County, Maryland. In this very affluent county, only 4 percent of the populace was then African American and only 7 percent nonwhite. Her constituents included top policy makers in Washington

and NASA staff from the agency’s Goddard Space Flight Center in neighboring Prince Georges County, Maryland. It was via her connections with Goddard that NASA Headquarters heard of her and hired her.15

Once she was vetted, security cleared, and hired, however, problems with Harris’s posting immediately developed. In fact, all this started before she had even officially left her post at the Montgomery County school system to report to work at NASA. Only one week after publicly announcing Harris’s hiring as a change agent with power, Fletcher demoted Harris and rehired her as an assistant deputy director rather than a director. Instead of enforcing change in an era of *Griggs* within a largely Southern agency, Harris reported to a white male overseeing private companies. Instead of regulating NASA, and in particular directors and deputy directors of NASA labs, Harris was sidetracked into an office dealing only with NASA contract employees and firms. Enforcing virtue upon itself had very quickly ceased being a NASA priority.16

Harris’s immediate demotion before she even arrived for work at NASA Headquarters on 4 October 1971 was a warning signal. It was also what NASA Deputy Administrator George Low later privately admitted was “the weakest part” of NASA’s official position. Nobody at NASA Headquarters ever accepted responsibility for the action. Lower echelons passed the buck to a man who had died.17

What had happened? Here, organizational culture and cultural context apparently interwove. NASA knew it had to do something about including hitherto largely unrepresented groups, but it also wasn’t comfortable getting started. NASA Headquarters staff also might have expected Harris to be a patient schoolteacher rather than the street-smart civil rights implementer that she was, networked into official Washington and to organizations such as the NAACP. One organizational statistic was eloquent: eight of NASA’s dozen major facilities had created equal employment/affirmative action offices just before Harris was hired. Four of the eight Center affirmative action people only worked part-time; all eight Center people were under the administrative control of lower-level procurement officers; and no fewer than six of the eight civil rights in Employment teams at NASA’s labs were all-white.18

NASA, then, talked about wanting “the best equal opportunity program in the federal government,” but using part-time and all-white organizations to do it was naïve. NASA employed fewer minorities and women than any other agency in government. It claimed this was because of its elite and expert technical structure, but far from everyone at NASA was a rocket scientist. This disparity between NASA and other federal agencies also grew even as African American professionals sought out government agencies as employers because those agencies also most often obeyed federal civil rights laws. NASA’s own statistics showed that it did as well as private corporations in employing minorities and women in the technical half of its operations (at 3.5 percent), but NASA’s leaders did not go on to ask why NASA employed only 6 percent of racial minorities in the nontechnical half of its operations. People like Harris were about to pose such uncomfortable questions.  

**Culture Shock**

As the newly arrived Ruth Bates Harris began investigating the human side of space exploration, she also almost immediately transgressed the unwritten folkways of a high-technology agency. At NASA, technical “missions” mattered; personal (and personnel) issues did not. Number Two man in NASA’s hierarchy and Chief “inside” Administrator George Low, for example, was so private a man that he never had a listing in *Who’s Who in America* during his NASA years, never spoke with reporters, and never let his closest aides at the Agency know keys parts of his background (which included being an Austrian Jewish refugee from Hitlerism).  

One reason for Low’s cloak of secrecy about himself shared offices at NASA Headquarters with him when Ruth Bates Harris arrived in 1971. Wernher von Braun, NASA’s premier missile man, had provided weaponry to a regime that had deemed the Lowensteins of Austria subhuman and deprived them of livelihood, homeland, and loved ones. Low, presented by von Braun’s most recent biographer as personally and professionally resentful of von Braun, said nothing publicly against him. His favorite managerial advice was for people to “put their emotional hang-ups aside.” To Low, like von Braun, “identity” issues were off-limits.  

---

Ruth Bates Harris’s approach to von Braun’s past was quite different. She didn’t intimidate easily and she was forceful. So, after reading in a newspaper story in 1971 or 1972 that von Braun had used slave labor to build rockets for the Nazis, she went straight to von Braun’s office to ask him whether the story was true. “The silence between us,” she recalled, “was deafening and awesome.” Von Braun finally replied that there were journalistic distortions. Harris said it was not her role to judge but that she was going to refer the story to an “appropriate office” at Headquarters. Von Braun, Harris then recalled, was both sad and understanding. Neither he nor Harris, after all, needed any instruction about how racism was not restricted to Nazis. Indeed, according to Harris, von Braun pushed for affirmative action “with courage and conviction” at the Center he had previously headed in Huntsville, Alabama. No other top NASA official of the era earned such praises from her. Yet, in officially bringing up von Braun’s past, Harris demonstrated more forthrightness than many of her contemporaries in NASA’s administrative hierarchy were comfortable with.22

Pressure Builds

Harris’s problems involved more than frankness regarding prohibited subjects. She also brought uncustomary issues into policy making, via her connections with the Congressional Black Caucus and the NAACP. NASA, for instance, had hired Africans over racist apartheid government opposition at South African tracking stations in the 1960s. But apartheid customs such as Africans eating outside while whites monopolized dining facilities continued. Given that the large majority of Earth’s population was not white, NASA might have to consider (as it eventually did) closing the stations.23

“Political” ideas like this did not endear Harris to those who saw space exploration as an obvious good that did not require modification. But the major problem with Harris was that she wanted her original job back. She also wanted to do what she had earlier done at the DC Council on Human Relations: transform a junior administrative post into a prominent leadership role after networking within NASA and between NASA and civil rights and women’s organizations.24

In early 1973, 8 months after her arrival, Harris clearly began pushing top NASA leaders beyond their comfort zones as she tried to implement policy regarding all executive-branch agencies obeying the same affirmative action laws as private industry. New civil service implementation rules also required affirmative action directors within agencies to report directly to top administrators of government departments to accomplish this.

NASA could not just simply ignore Harris. It had 5.6 percent minority and 18 percent female employees in 1973, versus a government average of 20 percent minority and 34 percent female. But of the 4,432 women that NASA employed, only 310 were in science and engineering and just 4—including Harris—were in the highest civil service grades. NASA’s technical culture could and did claim that female and minority engineers were scarce. But NASA did no better at hiring more numerous female and minority lawyers or nontechnical professionals (3.7 percent) than scientists and engineers (3.6 percent) in this period. NASA hired more minority male janitors (69 percent) than the government-wide average of 56 percent. But it hired no women at all to do this work and it trailed in all other occupational categories, from pilots to guards. What Harris, NASA’s highest-ranking woman, was saying about opening up NASA jobs and occupational hierarchies was legitimate and principled.25

NASA leaders, however, still didn’t want Harris to formulate or implement standards for the Agency. Instead, Fletcher and Low offered Harris a deal. They would raise her a level above that to which they had demoted her even before she arrived in office. She would be Number Two in a new equal employment opportunity (affirmative action) office and also Number Two in an office overseeing NASA contractors. She still would not report directly to either Fletcher or Low, nor would she be able to upgrade the inadequate affirmative action operations out in NASA’s Centers created just before her arrival. Harris didn’t like the offer, may have threatened to quit, and wanted her original job back.26

To Harris, NASA began to look like the uninterested at Headquarters leading the uncommitted in the Centers. To George Low, Harris was an administrative lightweight lacking the qualifications expected of a nontechnical assistant (rather than deputy assistant) administrator. This made NASA’s original hiring of her doubly curious. Harris’s qualifications were also equivalent to those of the men who were the assistant administrators for public affairs and international affairs at Headquarters at the time.27

By March of 1973, bureaucratic knives got whetted. Low privately commented that Harris’s affirmative action operation was a “dumping ground for poor people” who “could only say yes [to complaints] and not no.” Affirmative action, however, was “too low in the administrative hierarchy” and there was a “lack of management support and no leadership.” Low basically agreed with Harris’s administrative reasoning while arguing that she was a bad administrator.28

27. George Low, “Comments in November 14, 1973 Draft Letter to Senator Moss,” 19 November 1973, Box 35, Low/RPI (these men were, respectively, a Chicago businessman and a lawyer with the International Labor Organization).
28. Low to Fletcher, 15 March 1973, 3, Box 68; Low/RPI; Low, personal note no. 91, 14 April 1973, pp. 1–2, Low/RPI; Low, “EEO Contr Compl,” notes on the reverse of Low’s appointment book for 7 March 1973, Low/NHO; Low, personal note no. 91, 14 April 1973, p. 1, Low/RPI.
This meant Low had to find someone else to get more women and minorities hired, trained, or promoted within NASA. His eyes lighted on NASA’s only African American in a high level (or “super-grade”) scientific and technical position: Dr. Dudley McConnell of NASA’s Scientific and Technical Information Office.\(^2^9\) Two of Low’s aides told him and Fletcher that McConnell “would not want the job,” but Low persisted. Low, in fact, had hired McConnell into NASA as an aeronautical research engineer in Cleveland, Ohio, in October 1957. McConnell’s personnel or civil rights experience was far less extensive than Harris’s. He was also taken out of a senior science and technology position in which there were no other African Americans and put into an office where African Americans were not rare. But, in the end, McConnell agreed to accept the job Harris had originally been hired to do a year and a half earlier.\(^3^0\)

**McConnell Versus Harris**

Crude racism played no part in George Low’s decision, but the organizational culture of NASA clearly did. Low knew and trusted 16-year NASA man Dudley McConnell far more than he did M.B.A. and personnel/civil rights person Ruth Bates Harris. McConnell, wrote Low, understood the “problems of technical management” in aerospace. McConnell impressed a reporter for *Science* magazine who interviewed him as “soft-spoken, ingratiating, exceedingly articulate, and strong willed.” McConnell also compared himself to a ship captain with “unruly crew members.”\(^3^1\)

Turbulence was inevitable, given that Harris was a popular administrator and McConnell definitely was not. Only four months after McConnell took over in April of 1973, Low received two strong oral and written criticisms of McConnell’s managerial style from two departing staffers. McConnell didn’t relate well to women, “went for appearances rather than substance,” and was not communicating affirmative action “concerns to top management.” Because “seven or eight” other staffers “might soon be leaving,” Fletcher and Low both met privately with McConnell, after which Low privately concluded McConnell might indeed have problems with women and communicating concerns upward. Some of McConnell’s difficulties were unintentional. For example, he used a little bell to summon secretaries, who then lampooned him as “Mr. Ding-a-ling” (a silly, affected person). But McConnell’s major problem was that for the second time Ruth Bates Harris had now been denied the job for which she was originally hired. NASA’s new civil rights in employment chief, moreover, refused some of Harris’s early offers of cooperation.\(^3^2\)

\(^{3^0}\) Low, personal note no. 91, 14 April 1973, p. 2, Box 68, Low/RPI.

Discussion therefore soon became argument. Harris and her supporters began to believe NASA would enforce nothing on balky Southern labs. They also knew that organizations such as the National Urban League and the National Organization of Women were displeased by longstanding exclusions of women and minorities from the Houston-based Astronaut Corps. What Harris would later call NASA’s “pasteurized and insulated from the real world” aspects, moreover, made it harder to interest the non-male and non-white in space programs. McConnell, for his part, moved slowly, avoided confrontation, and ordered his staff not to undermine him.33

This is precisely what Ruth Bates Harris and two of her associates—Joseph M. Hogan and retired Air Force Colonel and Tuskegee Airman Samuel Lynn—did five months after McConnell’s too-gradualist tenure began. In September of 1973, the three sent an internal report to Fletcher they had prepared on their own time. In the process, they also did a bureaucratic end-run around McConnell’s sponsor, George Low.34

The Harris-Lynn report was frank, insistent, and began dramatically. NASA’s efforts were “a near-total failure.” The agency was denying that problems existed to avoid having to address them. Minorities and women stayed clustered in the lowest civil service job ratings. Thirteen of the 35 total minority hires of fiscal year 1972 were brought in at the lowest pay scale of GS-2. Three NASA Centers had not hired any minorities to do anything in 1972, all Centers in the South—the Kennedy Space Center, the Marshall Space Flight Center, and the Manned Spacecraft Center. Despite cutbacks, these same facilities had hired 10, 24, and 22 people, respectively, that year.35

Many considered affirmative action a “sham” at NASA because of uncommitted top management, “insensitive middle management,” and “unqualified, uncommitted persons” at NASA Centers. Some NASA installations simply were not going to hire African Americans or women or others until they were forced to. There was a “striking anomaly” between NASA’s technical genius and its social insensitivity. The only three females NASA had so far sent into space were two spiders and a monkey. “During an entire generation—from 1958 until the end of this decade—NASA will not have a woman or a minority astronaut in training”; this even as U.S. society was opening up to women and minorities in ways previously seen only during major wars that created labor shortages of white males. Dudley McConnell had demonstrated incapacity and “immaturity in relating to people” and should be removed. Then NASA’s human relations policies would begin to match its proven technical excellence.36

36. Ibid., the final paragraph, the “Preamble” and the “Special Concerns: No Minority or Female Astronauts” sections.
NASA Administrator Fletcher listened to his frustrated affirmative action staffers. He said vaguely agreeable things about further absorbing their message. Then axes fell. Fletcher fired Harris, transferred Hogan, and told Lynn to work with McConnell or resign. Fletcher claimed the firing and disciplinary actions had nothing to do with policy recommendations, all of which were “already well documented.” Instead, in a four-page, single-spaced memo sent to all NASA Headquarters staff, Fletcher presented Harris as a “seriously disruptive force.” Though a good advocate, Harris was an uncompromising ideologue who had sabotaged McConnell and NASA. NASA’s minority and female hiring record was not one in which it could take pride, but the future would be a marked improvement over the past.37

Harris was purged on 11 October 1973. For two weeks, things were quiet. Then the situation changed decisively after the 27th of October. In his private papers, Low made no connection whatsoever between Nixon’s purge of the Watergate special prosecutor on the 20th of October and NASA’s difficulties after Harris’s firing that involved NASA in far wider political struggles roiling all around it.38

NASA’s timing, nevertheless, was awful. Its leaders could not conceive that anyone would doubt their actions or motives, but plenty did. *The New York Times*, *The Washington Post*, three Senate committees, major African American newspapers, and local Washington radio and TV stations all featured the Ruth Bates Harris story shortly after Fletcher fired her. NASA blithely walked into a journalistic tree-shredder. Its press was so bad that Fletcher’s office forwarded to Low a “much more elegant than usual” story about the case from *Science* magazine from 23 November 1973, which Low should read.39

**NASA’s Political Beating Begins**

The *Science* article showed just how badly NASA had flunked politically. The author, Constance Holden, found the charges that Harris was disruptive or radical to be overblown. “It is difficult to imagine,” she concluded, “that it took NASA two years to discover that the woman was a ‘divisive’ personality.” “Fletcher’s Nixonesque purge” had only “opened up a can of worms” at NASA, Holden said. Seventy headquarters staff had already protested the firing, and civil rights and women’s groups at several NASA Centers were pledging support for Harris. A group called MEAN (Minority Employees at NASA) had been formed to protest employment conditions. Most importantly, the NAACP Legal Defense Fund was about to take on the Harris case to establish legal precedent regarding executive-branch agencies obeying affirmative action laws.40

38. Low, personal note no. 107, 13 November 1973, pp. 4–5, Box 67, Low/RPI.
39. “H” to Dr. Low, 20 November 1973, Low/NHO.
Things only got worse. An eventual 50 national organizations such as the National Conference of Catholic Charities and the National Organization of Women protested. So did prominent members of Congress. When Rep. Fernand St. Germain’s (D-Rhode Island) request for an explanation of Harris’s firing was simply ignored by Fletcher, St. Germain curtly wrote to Fletcher that his voting on NASA appropriations measures would be “equally unsatisfactory.” The Congressional Black Caucus protested and two Senate committees started making serious noise about scheduling hearings.41

Accordingly, by early December James Fletcher badly needed proof of Harris’s radicalism, so he sent Low and others off on a wild goose chase after he received a brief note stating, “We Black People do not want this Subversive person representing us—she is a known ‘Trouble Maker.’” Today, NASA handles claims like this the way it handles claims that it is hiding the truth about UFOs—the claims are politely dismissed. Fletcher, however, pressed for evidence of subversive associations but Low—via deniable intermediaries—was able to come up with nothing.42

As NASA chiefs belatedly realized the burden of proof about disloyalty might actually be on them, Harris gave interviews to reporters and her NAACP lawyers petitioned the U.S. Civil Service Commission against Harris’s dismissal as an illegal reprisal. NASA leaders had presumed that Harris was a political appointee they could fire at will; her NAACP lawyers cogently argued otherwise. In a climate of Constitutional crisis, any presidential agency claiming lèse majesté was suicidal. So NASA retreated and started paying Harris her full salary while her status was being determined.43

Simultaneously, Low was souring on the man he’d selected only six months earlier to run affirmative action. “Apparently,” he noted privately late in December, “McConnell has all the right ideas but he is not pushing very hard insofar as implementing these ideas is concerned.” Despite Low’s encouragement, McConnell was “still very slow.” “I think Fletcher and I will have to ‘lead him by the hand’ . . . until he can really run the show on his own,” Low concluded.44

41. Holden, “NASA: Sacking of Top Black Woman,” p. 806; Ruth Bates Harris, Harlem Princess, pp. 261, 263–264; St. Germain to Fletcher, 12 December 1973, Low/NHO. The National Organization of Women (NOW) only belatedly protested Harris’s firing. It provided Harris little or nothing in the way of financial or legal assistance. For NOW’s “often chaotic” internal organization in its formative years, see Freeman, The Politics of Women’s Liberation, p. 71ff. For NOW’s after-the-fact protest, see Senate Space Committee Hearings (1974), pp. 98–99.

42. Fletcher to Low, 14 December 1973 and M. Johnson to James Fletcher, 30 October 1973, Low/NHO; Low to Fletcher, 14 December 1973, Low/NHO; Unsigned memo from Low, undated (circa December, 1973) regarding report from Bart Fugler regarding “Concerned Citizens for America” group, Low/NHO.

44. Low, personal note no. 110, 23 December 1973, p. 7, Box 67, Low/RPI. For Low’s continuing belief that Harris was unqualified and his beginning awareness that he actually had to prove that point, see Low to “AD/Deputy Administrator,” 19 November 1973, Box 35, Low/RPI.
By January 1974, NASA’s yawning credibility gap got wider. NASA lawyers secretly told Low and Fletcher the Agency was probably going to lose its case against Harris and her NAACP Legal Defense Fund attorneys. It also faced the threat of class action suits from women and minorities. Crucial, here, was the unwillingness of those who had attacked Harris verbally to risk public exposure or legal repercussions. Despite requests from Low and Fletcher to repeat their charges to NASA (and NAACP) lawyers or to civil service representatives, they all refused.45

Within three months, then, NASA’s case against Ruth Bates Harris was in tatters. Blaming Harris wasn’t going to work, so the Agency therefore had a “pressing need” to make some progress itself. In January, Low pushed all NASA Center Directors to hire “at least one minority or female at the executive level [apiece] within the next 6 months.” Three Southern Center leaders in Texas, Alabama, and Florida refused, saying it was impossible to even begin. NASA had no operational and Agency-wide plan for recruiting or promoting women or minorities. NASA was being flayed in editorials in The Washington Post and elsewhere for trying to combat “institutionalized racism and sexism” with “simple pieties.” Worse, NASA was by now headed for political appointments on Capitol Hill with three powerful Senate bodies. First on the list was Senator William Proxmire of Wisconsin and the Senate Appropriations subcommittee he chaired, meeting on the 11th of January.46

Senator Proxmire was trouble, and NASA leaders knew it. He’d worked with Harris often on District of Columbia governance issues in the 1960s. He had also been a notable critic of NASA for a decade and didn’t care a whit for vague pieties. Accordingly, Fletcher and Low avoided testifying. Instead, they sent Dr. Dudley McConnell and two other managers in their places. Low, however, “... wrote Dudley’s [preliminary opening] statement since his was rather weak.”47

Harris and her associates Hogan and Lynn, meanwhile, argued far more openly. Hogan said NASA’s approach to hiring women and minorities was “calculated to provide the appearance of compliance while not doing so.” Harris added that NASA was now trying to take credit for proposals, such as recruiting minorities and women into the Astronaut Corps, that she, Hogan, and Lynn had made—this after punishing them and then doing nothing to actually create such a recruitment program. Finally, they said, McConnell had begun his tenure as affirmative action

45. Low, personal note no. 111, 6 January 1974, pp. 6–7 and Low, personal note no. 126, 18 August 1974, p. 8, Box 67, Low/RPI.

47. Low, personal note no. 112, 20 January 1974, p. 3, Box 67, Low/RPI. For Proxmire and Harris in the 1960s, see “Harris (1971–1),” p. 5ff.
head at NASA observing that forwarding civil rights in employment by “saying it was the law” was not a good idea, “...because NASA always breaks the law.”

Senator Proxmire then gave the hapless McConnell a political mauling, starting with the “always breaks the law” statement McConnell first claimed he couldn’t remember and later publicly apologized for making. No contractor compliance programs existed at key NASA Centers in Houston and Huntsville and no “show cause” orders had ever been issued to any NASA contractor. NASA representatives themselves used phrases like “somewhat poor performance” to describe their efforts. Senator Proxmire refused to accept NASA’s contention that it had not excluded minorities and (especially) women from the six groups of all-male and all-white astronauts it had already selected. The color line in professional baseball had fallen in 1947, and the civil rights era was now 15 years old, but NASA was willfully ignoring social change all around it. Dispensing with any pretense at political courtesy, Senator Proxmire said “Congressional monitoring” of NASA’s minority and women hiring programs would take place, effective immediately, via his subcommittee because of NASA’s “extremely poor record.”

Back at NASA, Low was oblivious to NASA’s and McConnell’s mauling. He used phrases like “not really unfavorable” and “in reasonably good shape” to describe NASA’s standing. Selective awareness and denials, however, did not lead either Low or Fletcher to want to personally attend the next hearing, this one by the Senate’s space committee. Aides now protested: both leaders absenting themselves looked bad. One or both needed to attend to maintain NASA’s fast-fading organizational credibility in the Harris case.

James Fletcher flatly refused. A Utah Mormon, Fletcher feared political and religious embarrassment, and with good reason. Mormonism had major problems with race and gender in the 1970s, and Fletcher wanted to keep himself and NASA removed from them. “Fletcher,” Low recorded on 20 January 1974, “...is particularly concerned because of his Mormon church affiliation and the fact that the new ‘prophet’ of the Mormon church has made statements that can be interpreted as against women and has also re-emphasized that the Mormon church will not admit blacks to ‘priesthood’ [and full membership in the faith].” Low and others argued that Fletcher was not in the Mormon hierarchy and would probably not

have any difficulty separating his personal beliefs from those of his faith. Fletcher, however, demurred. Mormonism’s racial exclusion practices, meanwhile, were not ended until 1978 (after Mormon leaders received their first divine revelation since polygamy was ended almost a century before).

Low, however, attended the second Senate hearing of January 1974 in Fletcher’s place. As he became higher-profile politically, Low also further distanced himself from the physicist he’d so recently and strongly supported over Harris. McConnell, Low observed, was “overwhelmed and overworked,” so Low pushed him to hire Dr. Harriett Jenkins, an educator, as a deputy. McConnell bridled, saying Jenkins was not a “professional in EEO [affirmative action].” Given that he wasn’t either, Low began wondering whether McConnell wasn’t “a little bit afraid” of Jenkins as a woman.

To test this hypothesis, Low had an aide talk at length with two senior African American women at the nearby NASA Goddard Center who had professional interactions with McConnell. Neither woman was impressed. “Apparently,” Low concluded, “[McConnell still had to] learn how to communicate effectively with people, especially women.” One of the women and a Hispanic section head at Goddard told Low’s aide that minorities and women really did believe NASA discriminated regarding promotions. One method the Kennedy Space Center then used particularly annoyed the Civil Service Commission: it had 43 different job rankings for secretaries, so women could thus be promoted but kept out of management ranks.

Austrian immigrant and political refugee George Low had remade himself in America. He believed “key people” at NASA’s Headquarters and its Centers would do the same. Low’s optimism, however, was not widely shared on Capitol Hill, where NASA’s political grilling about administrative unwillingness, unmet promises, and belated claims about future virtues continued. By 24 January 1974, NASA and George Low faced frank disbelief at hearings before a normally sympathetic Senate Aeronautical and Space Sciences Committee. Ruth Bates Harris’s performance at the hearings was calm and understated. Watergate was now consuming more and more Senatorial energies. Harris said NASA had failed in its duty to enforce laws passed by Congress. She and her supporters had “pricked the conscience” of NASA. “Institutionalized racism and sexism” existed there. The virtues NASA now claimed

52. Low, personal note no. 112, 20 January 1974, p. 4, and Low, personal note no. 113, 3 February 1974, Box 67, Low/RPI.

were belated and deceptive. NASA’s basic problem was that it was letting some of its Centers evade the law. It had not yet begun internal training and promotion programs for female or minority staff. It claimed it could not do what some unspecified percentage of aerospace contractors had already done: increase percentages of minority and women employees even as overall workforces declined.54

Harris’s performance earned compliments from the committee’s chair; Low and McConnell—who avoided being in the same room with Harris—got rougher treatment. Senators doubted that NASA Centers had any intention of doing what NASA Headquarters said it wanted. It didn’t help that the Department of Labor said it looked as if every NASA Center Director had their own “personal view of appropriate compliance policies and procedures.” Democratic Senators said NASA was “groping for sympathy” and setting “modest” goals it wasn’t really committed to.

It didn’t help that these goals [of hiring 80 more women and 80 more minorities in professional positions in its 25,000–person workforce in 1974] were decided upon only two weeks before the Senator Proxmire hearing that was held earlier in January. “Where’s your sense of urgency?” Senator Howard Metzenbaum of Ohio asked at one point. “He thought our performance was lousy and made no bones about it,” Low later recorded. The committee then, per Senator Proxmire, put NASA under legislative oversight. Affirmative action funding (also per Proxmire) was to double; NASA had to report on every major professional position it filled; and minorities and women were to be put on NASA hiring and promotion boards.55

NASA Fights On

Still NASA leaders fought on. Harris, NASA representatives told Senators, was “little more than a lobbyist for the cause of minorities and women.” Low privately believed Harris and “quite a few” of her supporters within NASA were sabotaging McConnell. The idea that she might be a lightning rod, not a thunderbolt, wasn’t considered. NASA’s top leaders now knew their case against Harris was legally lost. Nevertheless, in January they decided that she would never be rehired to her former position but, instead, only to a “comparable” post within NASA. If—and when—Harris won, she could be isolated and marginalized.56

Dudley McConnell’s days, meanwhile, were numbered. He still didn’t want Harriett Jenkins as a deputy, so Low got Fletcher to hire Jenkins himself. McConnell still resisted, offering at least one other female candidate the job after a weekend interview. Low then forced the issue to a final conclusion. Harriett Jenkins’s arrival at NASA wasn’t quite as messy as Ruth Bates Harris’s had been, but it demonstrated precisely the same organizational ambivalence and infighting.57

As Harriett Jenkins began working as McConnell’s deputy in February of 1974, the drumbeat of external and internal criticisms intensified. The chairman of the Civil Service Commission, for example, told NASA its record of processing racial and sexual discrimination complaints “was not very good.” The Department of Labor was similarly distinctly unimpressed with NASA’s record on oversight of civil rights in employment standards in firms it contracted with at its Centers. Recruitment teams for minority and female scientists and engineers still weren’t in place in at least four NASA Centers. Low’s orders to have entry-level jobs offered to likely candidates “on the spot” weren’t happening. A disappointed Low told a meeting of deputy Center directors called to jump-start affirmative action that “most of our technical managers were not accustomed to handling human problems.”58

Meanwhile, protest levels within NASA increased. The first training workshops regarding racial and sexual issues for senior Center leaders were scheduled for April and quickly got postponed. By March, top-level meetings were called to pick an affirmative action officer “more acceptable to women and minorities.” A selection panel should probably consist of three of NASA’s highest-ranking women, a Hispanic, and the NASA general counsel. They should “probably” pick a minority person as the affirmative action officer. Low was advising McConnell to return to technical work; trouble was brewing at NASA centers in Virginia and Texas; and Low was addressing all 1,000 NASA Headquarters staff at “communications” (morale-building) sessions. By May, NASA lawyers still advised settling with Harris; an outside consultant told Low and Fletcher they hadn’t done well regarding a “generally unstable headquarters situation since Ruth Bates Harris was terminated,” and Low wrote that “[O]ur people are still very much concerned . . . and have not seen that real progress has been made.” A Government Accountability Office (GAO) investigation based on interviews with NASA employees confirmed Low’s

57. Low to Fletcher, “Miscellaneous Items,” 21 January 1974; Low to Deputy Associate Administrator for Organization and Management, 5 February 1974; Low to Fletcher, “Harriet Jenkins,” 5 February 1974, all in Box 67, Low/RPI.

statement. No fewer than six Senate and House committees—including NASA’s authorization and appropriations committees in both houses—got copies of the GAO findings.59

So, after eight months, denials gradually began to end. In June of 1974, as Nixon’s presidency entered its final weeks, NASA and NAACP Legal Defense Fund lawyers sat down to hash out a settlement. Two sets of issues especially mattered. The first was organizational. Ruth Bates Harris and her counsel wanted—and got—enhanced training and promotion programs, monitoring of minority and female hiring at middle and senior management levels, and the beginnings of NASA research and development awards to Historically Black colleges and universities. Fletcher and Low refused, however, to give way on a key point. Harris wanted strong Headquarters managerial oversight and control over affirmative action at NASA Centers. This was the centralized job, of course, she had been originally hired by NASA to do. But Fletcher and Low refused, citing NASA’s “decentralized management concept.” Uncooperative Southern Centers got a breathing space.60

On a second set of issues regarding Harris’s personal administrative future at NASA, the Agency fought even harder. Harris still wanted what she’d always wanted: Dudley McConnell’s job. That meant policy-making power. NASA still didn’t want her to have this. She had embarrassed an agency that often saw itself in elite, even transcendent terms. To Low and Fletcher, she was an “advocate,” not a “manager.” Her skills were ignored. A senior management discrimination case at Headquarters, for example, had become explosive because of what Low called “three levels of poor management” where the white supervisors involved refused to take training in dealing with minority or female workers until Low “urged them to do it six times.” Harris, who had handled just such intensive “sensitivity training” programs for Washington, DC, police in the 1960s, was still persona non grata.61

Meanwhile, a protesting Dudley McConnell was pushed out of his job in June and July. Low was now de facto affirmative action head. The NAACP Legal Defense Fund threatened class action lawsuits on behalf of groups of employees at NASA Centers. NASA’s strongest House ally apparently told NASA the Agency’s political status was slipping. NASA could not win but it could not settle, either.62

59. Harvey W. Herring, “Meeting Record, March 29, 1974, EEO Officer, Low/NHO; “GAO Investigation of EEO Program,” 23 April 1974, Box 107; Low, personal note no. 117, 30 March 1974, p. 4; Low, personal note no. 118, 13 April 1974, p. 2; Low, personal note no. 120, 11 May 1974, pp. 7–8; Low, personal note no. 122, 8 June 1974, p. 11; “Notes for All Hands Meetings [April, 1974],” all in Box 67, Low/RPI.

60. R. Tenney Johnson, “Concerns and Views,” circa 5 June 1974, Box 67, Low/RPI.

Richard Nixon’s presidential resignation on 9 August 1974 seems to have helped prompt the combatants to settle. McConnell left office after 16 unhappy months; Harriett Jenkins promptly succeeded him. Ruth Bates Harris came back to NASA, but only at deputy assistant rank and only on the PR and community outreach fringes of the affirmative action office. It was what *Science* magazine termed “at least partial vindication.” On the 17th of August, Fletcher’s official statement welcoming back the woman he had fired complimented her “genuine ability to communicate to members of communities whom NASA has not reached in the past and whom we need to reach.” “[S]ome of the forward movement NASA . . . has made . . . ,” he continued, “has been stimulated by forces she so eloquently set in motion.” An uncompromising and disloyal ideologue now had redeeming importance.63

Verbal bouquets, however, did not make reacclimation any easier. Harriett Jenkins did not work with Harris (some of whose efforts involved identifying and recruiting African American astronaut candidates via aviation veterans’ organizations such as the Tuskegee Airmen). NASA’s rate of accomplishment remained “abysmally low,” George Low noted privately. Line managers had “not launched a significant effort” and top management had not made it clear to line and staff administrators what sanctions or rewards would apply to them. “What’s wrong?” a discouraged Low wrote on the margin of his first annual performance review with Harriett Jenkins. Pent-up tensions also levied a wider toll. Harris’s marriage dissolved and a son was stricken with AIDS. In 1976, Harris suffered a nervous breakdown and returned to New York to get her life back together. Fletcher and Harris smiled for cameras as she departed, but, after her return to Washington in 1978, she never worked for NASA again.64

**NASA Starts To Change**

The Harris deal ended further Senatorial hearings and negative journalistic coverage. All of NASA’s internal records on the Harris case were sealed as part of her rehiring agreement. After being legally and politically forced into more active compliance, NASA started congratulating itself on how well it was doing in hiring

---

and promoting more women and minorities. The basic norms, beliefs, and practices within NASA’s “human spaceflight culture,” however, only changed slowly. Female and minority supervisors at levels of GS–14 and above stayed rare until the 1980s. A false start at recruiting minority and female astronauts was implemented in 1978. The first female astronauts who “walked through the doors their activist sisters had pried open for them,” however, were hardly feminists. Skepticism and distancing only gradually turned into general acceptance by male astronauts. NASA had taken the right path after repeatedly denying it needed to do so; it thus got little credit for belated understanding.65

Meanwhile, the new head of Headquarters Civil Rights in Employment, Dr. Harriett Jenkins, had to operate in an organizational landscape littered with fears and grudges. Two vignettes show how her organizational style remained nonconfrontational and gradualist. First, in February of 1975, an affirmative action meeting for top Center heads was finally held, almost a year late. During that meeting a white manager was “quite rude” to Jenkins. The abuse was thorough enough that a normally undemonstrative Jenkins broke into tears and later asked Low for managerial support. Low gave it, but then his initially concerned comments turned flippant. After talking with the all-white deputy Center directors at the meeting, he privately dismissed female and minority objections to Jenkins’s treatment as overreaction. Given NASA’s “abysmally slow” record since 1971, Low’s turnaround was precisely the kind of group denial that had cost Ruth Bates Harris and Dr. Dudley McConnell their jobs. Jenkins was going to have to proceed carefully to survive for long.66

In case she had any doubts, another indicator of just how far NASA had to go occurred late in 1975. Jenkins and her associate, Peter Chen, proposed an affirmative action training session “for NASA’s senior [Headquarters] management from Fletcher and Low on down.” They wanted a one-day session led by two specialists from Arthur D. Little, a well-known management consultancy. Fletcher and Low had a preliminary meeting with the A. D. Little people and came back utterly opposed. Specifically, they did not want any kind of policy discussions or consciousness-raising where disagreements among senior staff might be identified.

65. Kevles, Almost Heaven, esp. p. 69ff; Weitekamp, Right Stuff, Wrong Sex; and Ackmann, The Mercury 13, also briefly cover the opening of the astronaut Corps to women. Only Kevles very briefly mentions Harris as a change agent (see pp. 58–59). For opposition to female astronauts, see Mike Mullane, Riding Rockets: The Outrageous Tales of a Shuttle Astronaut (New York: Charles Scribner’s Sons, 2006), esp. pp. 36ff, 346–347, 357.

Because the A. D. Little people “tried to drive a wedge between Fletcher and me, and put Fletcher on the carpet for not knowing as much as I did about the situation in NASA, [they were] not the right kind of people for a NASA training session,” Low concluded—especially because they might also drive wedges between Low and Fletcher and their senior staff, which would only be “counterproductive.”67

Because precisely such differential understandings and actual or contrived ignorance were what the affirmative action mess at NASA was all about, Fletcher’s and Low’s refusals ensured more policy muddle within Headquarters and Center managerial hierarchies. They also implied that the men leading NASA had nothing significant to learn or agree about. Those, for instance, who only saw racial or sexual bias when white males were excluded from competitions could continue to do so. When Low told Jenkins and Chen this, Jenkins did not protest, but her associate did. Low’s unusually graphic notes then describe the scene:

I said that they must realize the implementation of EEO [affirmative action] activities at NASA is my responsibility in accordance with policies which were established by Fletcher. Peter [Chen] took issue with this and said that if Fletcher were [sic] not going to run EEO in NASA and be personally involved in its implementation, it would never succeed. I very deliberately got mad at Peter, told him if he didn’t like the way I was running things, he could march right into Fletcher’s office and tell him so, but until Fletcher directed me to do differently, I would continue to be in charge. Peter did not take me up on my offer to go see Fletcher, and as a matter of fact backpedaled very nicely.68

Given the fate of Ruth Bates Harris, Chen’s (or Jenkins’s) reluctance to appeal over Low’s head to Fletcher was understandable. Low, however, was no cardboard villain. He knew what racism was and had survived Hitlerism. Additionally, his efforts to get NASA to start addressing the problems Harris and her allies identified were relatively strong and sustained as compared with others of his managerial era. On the eve of his departure from the Agency in 1976, for instance, he sponsored an unusual three-day retreat for senior NASA managers. At this meeting, Noel Hinners of the Office of Space Science was unusually frank. “A successful filtering mechanism in the information channel is a major problem,” he began. “Many people believe that real problems are being submerged [or dealt with impatiently].” Problems were also “covered-up so top managers won’t know.” Finally, Hinners added, “[T]here is a failure to face up to personnel problems by many managers who don’t like to discuss such issues with their own people.” Here was most of NASA’s unhappy early experience with minorities and women in a nutshell.69

67. Low, personal note no. 156, 13 December 1975, p. 9, Box 65, Low/RPI.

The Harriett Jenkins Era, 1974–1992

Affirmative action’s new head at NASA, however, possessed key advantages her predecessors Harris and McConnell had not. The most important was timing. Harris had “lanced the boil,” as Jenkins later put it. Built-up emotional pressures had begun to decrease as decades of denial began to end. Pioneering affirmative action/EEO managers such as Harris had jarred and infuriated people, and their casualty rates were very high. Succeeding managers such as Jenkins avoided Harris and gradually operated in a less strife-filled environment. Generational change was a factor. By the 1980s, the founding generation at NASA, who grew up in a segregated and apartheid America in which women rarely existed in aerospace and never gave adult males orders about anything, were retiring and dying.70

Harriett Jenkins also benefited because she was the patient teacher, in personality and bureaucratic approach, that NASA Headquarters may have thought it was getting when it originally hired Harris in mid-1971. Born in Fort Worth, Texas, Jenkins went to Fisk University in Nashville, Tennessee, on a scholarship. Graduating with a mathematics degree in 1945, she joined her sister in California, where she worked in clerical roles for the Air Force, an insurance company, and the Oakland Police Department from 1948 to 1954.71

Jenkins’s real occupational journey began in 1954, the year in which the Supreme Court, in Brown v. Topeka, ruled that educational segregation should end “with all deliberate speed.” Jenkins promptly applied for a high school teaching position in the public schools of neighboring Berkeley, California, a notable university town. Notable or not, Berkeley’s public schools also excluded African Americans from relatively senior teaching jobs at that time. However, Jenkins did not give up. If one tactic didn’t work, she tried another. Taking several years to earn a certificate in elementary education, she applied again and proved herself in the Berkeley system with a second-grade class which had “sent two previous teachers home” in despair. Rising quickly through the ranks as Berkeley slowly and peacefully addressed varieties of de facto school segregation, she became the city’s first female African American vice principal, director of elementary education, and finally assistant superintendent of schools. Along the way, she earned her master’s in education at the University of California-Berkeley in 1957 and her doctorate in education there in 1973.72

That same year, Jenkins followed her second husband, a career military man, to Washington, where she worked as a consultant before going to NASA. Typically, Jenkins did not confront power; she educated it via alternate routes. While Ruth Bates Harris had charisma, challenging people to energize and motivate them, Harriett

70. Dr. Harriett Jenkins interview with author, 25 August 2005, Bethesda, MD.
Jenkins emphasized thoroughness and patience. Harris spoke of “changing the system” that made discrimination against many groups possible. Jenkins, in contrast, preferred value-neutral phraseology like “increasing the pool” of qualified applicants. The only NASA Headquarters man who officially honored Harris’s efforts at opening space exploration to women and minorities in the 1980s was himself fired for including actress Jane Fonda in a bipartisan group of influential women invited to the launch of first female astronaut Sally Ride in 1982. From then until her death in 2004, Harris was—at best—a footnote in NASA’s organizational memory of itself.73

As Harris (and McConnell) lapsed into invisibility, Jenkins’s 8-year tenure at NASA Headquarters left her with honors from the Agency, from women in aerospace science and engineering organizations, and from the Congressionally chartered National Academy of Public Administration. Moreover, after Jenkins left NASA she became the director of the Office of Fair Employment Practices for the U.S. Senate from 1992 to 1997. She has continued to do consulting work for NASA and other organizations.74

Jenkins was honored and Harris was forgotten because Jenkins was a nonconfrontational gradualist. Key, here, was her willingness to work within a decentralized NASA structure and with a Center-oriented Equal Opportunity (affirmative action) Council of deputy directors of NASA labs, joined with staff from Jenkins’s Headquarters office. New York–raised Harris had always opposed this approach, seeing it as one more tool for noncompliance by Southern labs and reactionary middle managers who screened matters from upper echelons. Native Southerner Jenkins seems to have assumed that lower levels of compliance were a shorter-term given, one that would be gradually addressed in programs and plans taking 10 to 15 years to come to fruition. Harris and her allies wanted to force Centers to stop stonewalling and start doing things. Jenkins and managers like her, with a process of sometimes reluctant accommodation under way, wanted NASA Center managers to buy into the concept that diversifying NASA’s labor force was a key part of their jobs, not some radical, liberal excess that would promptly be ruled unconstitutional when legislators and judges came to their senses. Jenkins’s nonconfrontational “What can we do for you?” approach to Center Directors was part of this Fabian strategy. Harris was shocked that a twentieth-century science- and engineering-based Agency had significant numbers of people in it with nineteenth-

73. To illustrate the point about Harris’s historical disappearance, no prominent obituaries appeared when Ruth Bates Harris died in 2004.

century habits of mind. Jenkins already knew, from her experience as a teacher and a school administrator in an elite university town, that very smart people could be very ignorant outside of their areas of expertise. Harris was a primary change agent whose firing and rehiring forced NASA to issue quarterly reports on its hiring of women and minorities to Senator Proxmire and Congress generally for three years. Jenkins made it possible for NASA to slowly move on once Senator Proxmire’s reporting requirements were removed in 1978.75

**Conclusion**

Thus, the American space program went coed and multiracial. In 1974, women and all minorities combined comprised about 5 percent of the science and engineering workforce of a high-technology agency. As physical sciences and engineering education very slowly opened up to women and nonwhites, these numbers increased, especially for nonminority women and Asian Americans of both sexes. In 1983, Harriett Jenkins wrote Low on NASA’s 25th anniversary to tell him about the progress she had made in her first 10 years of integrating women and minorities into NASA’s labor force. Jenkins’s effort mixed flattery and bureaucratic self-advertisement with a sure hand. She talked about how in a decade nonminority women had risen from 15 percent to just under 18 percent of NASA’s total, while minorities had doubled from 6 percent to 12 percent. In the science, engineering, and technical half of NASA, the equivalent percentages were increases from 2.3 percent to 5.5 percent for nonminority women and from 3.9 percent to 8.3 percent for all minorities. Calling this “modest progress,” Jenkins went on to tell the man who had done more than anyone else to bring her into NASA that “[T]he greatest challenge still plagues us—the placement of minorities and women in the senior levels of the agency.” The 1980s, Jenkins hoped, would accelerate gains because of sympathetic leaders within the Agency in the Reagan era. Complimenting Jenkins’s work, Low replied that “the pipeline is filling rapidly” with female candidates qualified for upper managerial ranks, but that the problem of minorities remained “more difficult.”76

So it was in the nation, in physical sciences and engineering education and occupations generally, and at NASA. The 1980s, as Low expected, saw a gradual increase in nonminority female (and also Asian American) numbers, while progress for other groups remained slower. By 1991, about 12 percent of all NASA science and engineering jobs were held by nonminority women; about 5 percent by Asian

76. Harriett Jenkins to George Low, no date (circa November 23), with attached statistical sheets; Low to Jenkins, 14 December 1983 (both in Box 138, Low/RPI).
Americans; and about 4 percent each by African Americans and Hispanics. NASA, like the rest of the U.S. society around it, was gradually opening up to new groups and constituencies. NASA Administrator Dan Goldin flustered many in his agency when he announced in 1994 that the Agency was still too “male, pale, and stale.” But important initiatives such as the Science, Engineering, Mathematics and Aerospace Academy program for precollegiate minority and female students that began in 1993 later went national at NASA because of the efforts of NASA officials like Goldin and Jenkins. It also got NASA to establish more serious university research center relationships with Historically Black colleges and universities in 1995. It took until 1999 for Air Force Colonel Eileen Collins to command a Space Shuttle mission but, 42 years after Sputnik, it happened. Problems remained, though. The largest gender gap for any science and technology issue measured by the National Science Foundation in 2000 was in space exploration (14 percent). The under-representation of women and minorities in the physical sciences and in engineering especially mattered.  

The bottom line here is that women and minorities comprise nearly two-thirds of the population and a majority of the American labor force, but only a vastly smaller share of its high-technology and science skills pool. In physics (14 percent) and engineering (8 percent), it is still rare to find a woman holding a Ph.D.-level job. The quarter of the nation’s science and engineering workforce that is female has also changed little in the last decade. The growth of science and engineering graduates among minorities is still very slow. In a decade when an estimated half of all NASA employees and a quarter of all NASA engineers will be eligible for retirement, and in which noted trade journal *Aviation Week & Space Technology* reports that the average age of aerospace workers in American corporations is the early 50s, recruiting and utilizing historically under-represented groups may be only intelligent selfishness in the longer run, for NASA or for any other organization, which is “an investment in America’s future.”

A person who makes this latter argument cogently and well is Dr. Shirley Ann Jackson, president of Rensselaer Polytechnic Institute (RPI) in Troy, New York, and the first African American Ph.D. in physics from MIT. That Shirley Ann Jackson

assumed her presidency in the same year as Eileen Collins commanded her space mission is no historical accident. The fact that she also succeeded NASA’s George Low as a successful and honored president of RPI also has a lot to do with the change era described in this paper. As scholars have recently noted, the early 1970s were a period in which the “woman question” wouldn’t go away, inside or outside of NASA. It was also a period during which an all-male and all-white Astronaut Corps came to exclude too many other Americans. NASA’s human spaceflight program would have ceased being “manned” and become “human” without Ruth Bates Harris or her supporters, but it would have taken significantly longer than the 20 years it did take. NASA and America’s space programs would only have been poorer for it, in terms of public interest, understanding, and regard. Ruth Bates Harris deserves to be remembered as an important actor in the social history of the Space Age.79

On 19 September 1961 NASA Administrator James E. Webb announced that the Agency’s Manned Spacecraft Center, which would serve as the command center for the Apollo missions and future human spaceflight programs, would be located near Clear Lake in southeast Houston, Texas, on 1,020 acres of land donated to the government by Rice University. Following the announcement, Congressman William C. Cramer of Florida and Senator Benjamin A. Smith of Massachusetts cited political pressure from influential Texans (including Vice President Lyndon B. Johnson, who headed the Space Council, and Texas Congressman Albert Thomas, whose district included Houston and who controlled NASA’s funds as chairman of the House Appropriations Committee) as the reason why Houston was selected as the site for the NASA Center. During the next year, members of the Space Task Group transferred from the NASA Langley Research Center in Hampton, Virginia, to Houston, where they worked in temporary facilities throughout the city while awaiting the completion of the federal laboratory.¹

When President John F. Kennedy arrived in Houston on 11 September 1962 to see the construction of NASA’s Manned Spacecraft Center (MSC) and visit Rice University, he greeted nearly 200,000 Texans at the city’s airport by saying:

I do not know whether the people of the Southwest [Texas] realize the profound effect the whole space program will have on the economy of this section of the country. The scientists, engineers, and technical people who will be attracted here will

¹. The Houston Chronicle, 19 September 1961, 20 September 1961; The Houston Post, 20 September 1961; “Houston Manned Spacecraft Center,” 10 September 1962, NASA 1960s Vertical Files, Houston Metropolitan Research Center, Houston, TX. An additional 600 acres of land were purchased by NASA in 1962.
really make the Southwest [Texas] a great center of scientific and industrial research as this nation reaches out to the moon. In this place in America [Texas] are going to be laid the plans and designs by which we will reach out in this decade to explore space.\textsuperscript{2}

The president’s promise was impressive and the prophetic statement came true as the Agency’s decision to establish a center near Clear Lake propelled Texas into the Space Age by transforming rural towns in the area into highly visible communities that surrounded a unique facility for the training of astronauts and the control of their spaceflights. During this period of rapid growth, local businesses and nearby schools flourished. The federal installation also brought millions of dollars and enticed highly educated technical specialists into the area. The relocation of national aerospace companies to the Clear Lake area created new jobs and the need for more support services, which primarily added to the diversification of Texas’s and the Gulf Coast’s economy. The close relationship that the MSC established with local academic institutions expanded their graduate programs, accelerated their research projects, and enlarged their curriculums to meet the needs of the space program. The immense effects that the installation had on Texas ranks alongside other notable events in the state’s history, including the discovery of oil at Spindletop, the opening of the Houston ship channel, and the creation of the petrochemical and refining industries following World War II. NASA indeed launched Houston into orbit by contributing to the population, economic, scientific, and technological buildup that the region experienced during the 1960s.\textsuperscript{3} This essay focuses on southeast Texas between 1961 and 1969 in an effort to demonstrate how the federal complex represented a catalyst to Houston’s economy and enhanced the area’s colleges and universities.

Prior to NASA’s decision to locate a research facility in Houston, the Clear Lake area had population of 6,520 people. Most of the land in the region, which sold for less than $750 an acre, was devoted to cattle and agriculture. There were also several producing oil and gas fields in the adjacent town of Friendswood. The largest nonagricultural industry was oyster and shrimp fishing, which was centered in the neighboring communities of Seabrook and Kemah.\textsuperscript{4}

As a direct result of the MSC location, the Humble Oil and Refining Company and Del W. Webb formed the Friendswood Development Company to create a planned community, known as Clear Lake City, on 15,000 acres of land adjacent to the Center. During the 1960s, the development company oversaw the construction

\textsuperscript{2} The Houston Press, 12 September 1962.
\textsuperscript{4} The Houston Post, 28 August 1977; Dave Lang, “Impact of MSC on the MSC Area,” October 1966, Economic Impact Study, Lyndon B. Johnson Space Flight Center, Management Analysis Office, Management Analysis Studies, NASA Record Group 255, National Archives and Records Administration—Southwest Region (Fort Worth, TX); The Houston Chronicle, 11 October 1961.
of office buildings, service stations, restaurants, motels, shopping centers, banks, a
golf course, a recreation center with swimming pool and baseball field, apartment
complexes, and hundreds of homes. With all of these amenities, many of the leading
scientists, engineers, and technicians working at the federal laboratory made Clear
Lake City their home. By the late 1960s, the area’s population exceeded 45,000
people and land values had skyrocketed as half-acre sites sold for more than $6,000.
Aside from the rapid growth and booming land prices, the area’s economy benefited
from the $100-million development project because Houston developers utilized
local labor to construct the residential subdivisions and commercial buildings.5

Just across the road from the NASA Center were lush pastures owned by
Colonel Raymond Pearson. With the need for additional housing and commercial
facilities to be built around the MSC, a group of Houston businessmen sought to
capitalize on the area’s rapid development by purchasing a 570-acre tract of land
from Pearson to develop a community known as Nassau Bay. On 15 September
1963 David Bell, who was an aerospace technologist working at the MSC, and his
family became the first residents of Nassau Bay. As other NASA employees and
workers from the local aerospace companies moved into the development, Nassau
Bay’s residential sales exceeded $5 million by the fall of 1964. Aside from residential
homes, Nassau Bay also included shopping centers, a bank, several apartment units,
two motels, a post office, and an office complex which housed the MSC’s press
corps and more than 25 space-oriented firms. Additionally, the community had
its own telephone company and a power plant operated by Thermal Systems Inc.,
which supplied year-round metered air conditioning and heating to the commercial
buildings, townhouses, and apartments.6

Established communities near the NASA site also shared in the land boom
during the 1960s. Prior to the construction of the MSC in Houston, Hurricane
Carla struck the Texas coast on 11 September 1961, which destroyed most of the
Seabrook community and discouraged many of the local residents from rebuilding.
Thus, the area soon became a ghost town. However, news of the federal government’s
plans to establish a NASA facility nearby revived the community’s hopes and spirits.
During the 1960s, Seabrook experienced rapid growth as NASA employees and
aerospace company contractors moved to the area. By 1967, the Seabrook Chamber
of Commerce reported that the town’s population exceeded 5,400 residents. As

February 1965.
Seabrook’s population continued to increase, the community needed additional facilities and services to accommodate the new influx of citizens. Therefore, the once-quiet fishing village witnessed the construction of new shopping centers and subdivisions that included 100 new homes and 1,000 apartment units. Road conditions were also improved in Seabrook when a two-lane drawbridge was built over the Clear Creek channel that connected Clear Lake with Galveston Bay.7

In 1960, Friendswood, which was 10 miles west of the Center, represented a small rural town of about 75 Quakers who were living off the Texas oil boom with mainly an agricultural lifestyle. When the MSC was built in the Clear Lake area, the small town developed into a suburban community as new residents moved to the area.8 Dramatic growth led to the construction of two water wells, a new sewage disposal plant, several subdivisions, shopping centers, and a new drugstore. Other notable town improvements included the establishment of a new medical clinic, which housed Friendswood’s first doctor and dentist. Many of the MSC employees and aerospace contractors, including Director of Flight Operations Christopher C. Kraft, Jr., Flight Director Glynn S. Lynn, and astronaut Donald K. Slayton, made Friendswood their home. By the late 1960s Friendswood was no longer a quiet country village, but the Quaker influence was still visible within the community because local grocery and convenience stories did not sell alcohol.9

The economic impact of the MSC on Houston was felt immediately as national aerospace companies established regional marketing, service, and engineering liaison offices in the area.10 Robert H. Brewer, who served as manager of the Houston Chamber of Commerce, said this represented “one of the greatest concentrations of national corporate interests brought to focus on a single major metropolitan area in so short a period of time.”11 By 1966, more than 125 firms had established offices in the Clear Lake area. Among the largest space-oriented companies were the Philco Houston Operations of Honeywell Inc., North American Aviation Inc., General Electric, Lockheed Electronics Company, International Business Machines’s Federal System Division, Raytheon Company, Thompson Ramo Wooldridge (TRW) Systems Inc., Volt Technologies Corp., the Univac Division of Sperry-Rand,

10. Letter, Fred Staacke to Kenneth S. Pitzer, 30 January 1962, The Kenneth Pitzer Papers, Box 11, Woodson Research Center, Fondren Library, Rice, University, Houston, TX.

Beckman Instruments Inc., Texas Instruments Inc., and Federal Electric Corp. At first, the firms came to Houston to work exclusively with the Agency, but many of them stayed as the Apollo program drew to a conclusion because they viewed the area as a new base for expansion and diversification. During the late 1960s the companies provided their services to the nearby petrochemical industries and engineering businesses in the Houston area. Thus, the space-oriented firms assisted in diversifying Texas’s economy. However, a majority of these companies are no longer in business today as budgetary constraints in the space program forced them to close operations or consolidate with other aerospace firms.12

Aside from national research and development companies relocating to the Clear Lake area to compete for the Agency’s contracts, new businesses were established and others were expanded to provide supplies, equipment, and services to the Center. In January 1962, Gulf Aerospace Corp. was one of the first companies to be organized as a result of the NASA facility. The firm received a contract from the Agency to develop medical equipment designed to monitor an astronaut’s heart rate during spaceflights. Another enterprise was the A-OK Business Service, which was established in Houston to provide secretarial and telephone answering services for the institution. By 1967, the firm expanded its operations by providing a placement service for temporary and permanent employees in adjacent Harris and Galveston Counties. Other companies included Test Equipment Corp. and Geo Space Corp., which provided electronics support for the space-oriented firms in the Clear Lake area. By the late 1960s, the total amount of NASA contracts awarded to these companies, along with other Houston-based businesses cooperating with the MSC, was more than $643 billion, which was poured directly into Texas’s economy. Thus, the federal funds encouraged and supported future growth and expansion in southeast Texas.13

More meaningful to the Houston and Clear Lake area economy was that local firms obtained contracts and awards for space-related projects and construction work at the NASA Center.14 Among the first Houston companies to receive a

---

NASA award was Brown & Root Inc. In February 1962 the construction company was the recipient of a $1,499,280 contract for architectural design work on the MSC. Other local engineering firms to benefit from the Agency’s awards was S.I.P. Inc. of Houston, which was awarded a contract for $272,522 to build and install a space environmental chamber at the NASA facility. Following the successful flight of Apollo 8, NASA awarded the Houston-based A-V Corp. a contract to develop a documentary that utilized the first close-up motion pictures of the lunar surface. In 1966, Warrior Constructors Inc. of Houston and the National Electronics Corp. of Houston were the recipients of a NASA contract for $4.3 million to construct and equip the Lunar Receiving Laboratory, which would house the returned lunar samples collected by the Apollo astronauts.

While economic growth and progress was transpiring near the Clear Lake site, colleges and universities throughout the Houston area witnessed these benefits and viewed the establishment of a permanent relationship with federal research complex as a way to enhance their academic prestige and prosperity.

Rice University in Houston was one of the initial educational facilities in the area to be influenced by the arrival of the NASA complex. On 4 January 1963 Dr. Kenneth S. Pitzer, who was president of the 70-year-old university, announced the establishment of the Space Science department at Rice. Prior to the announcement, several institutions around the United States, including the University of California at Berkeley, the University of California at Los Angeles, the University of Michigan, and the University of Maryland offered postgraduate work on the subject, but these programs were usually only part of a physics department or of a college-affiliated space research center. Therefore, Rice represented the only college or university in America to have a department devoted exclusively to space science. MSC Director Robert R. Gilruth welcomed the establishment of the new department at Rice University. “We expect it to be of great assistance in carrying out the mission of the Manned Spacecraft Center,” he said. The benefit of the Space Science department would result from being able to train highly specialized professional and technical NASA employees at Rice University,

19. The Houston Post, 11 March 1962; Wesley L. Hjornevik, interview by Robert B. Merrifield, 9 March 1967, 1 July 1967, and 9 September 1967, transcript, Center Series Interviews, JSC History Collection, University of Houston–Clear Lake, University Archives, Houston, TX.
which was less than 40 miles away from the federal site, instead of sending them to institutions on the either the West or East coasts.22

Rice’s Space Science department provided research and graduate-level instruction in geomagnetism, Van Allen radiation, aurora, atmospheric structures and dynamics, planetary structures, and meteorites.23 Dr. Alexander J. Dessler, who was appointed chairman of the new department, stated that the establishment of a Space Science department had a large regional value because it expanded space research in the state of Texas and contributed to making Rice University one of the top academic institutions in the nation.24

The Space Science department grew remarkably during the 1960s. For instance, the faculty expanded from 4 in the spring of 1963 to 17 by December 1967. The graduate student enrollment increased from 9 in September 1963 to 50 in three years. Many of the graduate students who enrolled in the Space Science department were MSC employees and local aerospace contractors who sought to broaden their understanding of sounding rockets, satellites, astronomy, planetary and meteoritic structures, quantum mathematics, and astrophysics.25

Aside from being the recipient of several NASA research grants, Rice also cooperated with the MSC by providing research and teaching facilities for the scientist-astronauts, where they were able to maintain proficiency in their specific fields of study while they were involved in astronaut training at the NASA Center. The close proximity of Rice University and the MSC made the research facilities at the institution convenient to the scientist-astronauts so they could keep up with their scientific work without involving extending amounts of travel time.26

One of the most notable outgrowths of Rice’s Space Science Department was that NASA awarded the university a $1.6 million grant to construct a Space Science and Technology Building to house the institution’s rapidly expanding research activities. The building consisted of offices, conference rooms, a high-speed computer center, environmental testing facilities, materials research facilities, and a low-level radiation laboratory. During the late 1960s, 18 faculty members, 31 graduate students, and 10 postdoctoral students worked on 35 space-related projects, including meteorite experiments, cosmic rays measurements, solar wind investigations, and aurora studies in the Space Science and Technology Building. The success of these projects enabled Rice to become the first college or university in the United States to receive approval from the Agency to design and development its own satellites under the new University Explorers Program sponsored by NASA. Although Rice University was ranked as one of the top 20 academic institutions in the nation prior to the arrival of the MSC, the close partnership that the university developed with the Center enhanced the school’s national and international prestige.

The success of the Space Science department also contributed to Houston developing a new image that never existed before the 1960s. The city had always been viewed as the center of the oil and gas industry, but Rice’s program and the MSC caused the nation to recognize southeast Texas as a site for space-oriented research and development.

Probably one of the greatest impacts that NASA had on Rice University was that the national government passed a resolution in July 1963 which stipulated that after 16 August 1964, federal agencies were restricted from awarding contracts to colleges or universities that discriminated because of race, creed, color, or national origins in their admission process. At this time, Rice University was the only

nonsectarian, private institution in the South that prohibited the admission of African American students. Thus, President Pitzer and the Board of Governors recognized that if they failed to remove racial restrictions on student admission, the university would suffer the consequences of losing NASA grants. The possibility that Rice could have become ineligible to receive research funds from the Agency represented an ironic twist because one of the main reasons why the NASA installation was centered in Houston was the availability of Rice’s scientists and research facilities.

In February 1964 the Rice trustees filed a petition asking for District Court authority to disregard racial restrictions set out by the university’s founder, William Marsh Rice, in an 1891 indenture. The trustees claimed that race discrimination prevented the institution from receiving federal research grants and hampered the recruitment of first-rate students and faculty members. A Rice alumni group headed by Congressman Albert Thomas, whose district encompassed Rice University, also filed a petition in support of the trustees’ request. On 11 February 1964 District Judge William M. Holland of the 127th District Court heard Rice’s case. During the suit, Tom Martin Davis, who was the attorney for the university’s trustees, argued in favor of integration by stating, “Rice University today stands at the crossroads—it could go to the moon or it could return to the 19th century.” After the jury deliberated, they found that it would be impossible for Rice University to develop as a first-class educational institute if African Americans were barred from enrollment. A month later, District Judge Holland ruled that Rice University’s trustees had the authority to remove racial barriers prohibiting the admission of qualified students. With the desegregation of Rice, the institution became eligible once again to receive NASA research grants. In the spring of 1965, Raymond Johnson became the first African American to be admitted to Rice University.

The arrival of the MSC in Houston also led to significant changes at the University of Houston. During the early 1960s the academic institution witnessed the close relationship that existed between Rice University and the Agency, so

34. The Houston Press, 8 January 1964.

40. The Houston Post, 10 March 1964; The Houston Chronicle, 9 March 1964.
the University of Houston expanded its interests and needs to keep pace with the Space Age. For instance, the university inaugurated doctoral programs in physics, mechanical engineering, and electrical engineering after recognizing the need for higher-trained personnel in these fields.\footnote{The Houston Post, 8 September 1963.} Dr. Clark Goodman, a professor of physics, developed a course entitled “Aerospace Science and Engineering,” which focused on space environments, temperature controls, heat protection, and launch vehicles. In the fall of 1963 nearly 40 graduate students and seniors enrolled in the course. Aside from Goodman’s daily lectures, students had an opportunity to discuss the current activities and operations at the NASA Center with MSC officials, including Maxime A. Faget, who served as Assistant Director of Engineering and Development; Bryan R. Erb, who worked in the Structures and Materials Branch; David M. Hammick from the Space Technology Division; and Chief of the Space Radiation and Space Environment Division Jerry L. Modisette. This new space engineering class at the University of Houston represented one of the first courses of its type in the nation.\footnote{The Houston Press, 23 October 1963; The Houston Press, 24 September 1963.}

Aside from this course, the university jointly sponsored a variety of educational and research programs with the NASA complex, such as the Summer Faculty Fellowship Program, Sustaining University Program, Employee Graduate Training Program, and Pre-doctoral Traineeship Program.\footnote{“A Study of NASA University Programs,” 1968, The Philip G. Hoffman Papers, Box 35, Special Collections and Archives, University of Houston Libraries, Houston, TX; R. W. Hough, “Some Economic Impacts of the National Space Program,” (Washington DC: NASA-CR-96809, NASA, 1968), pp. 35–36; “Material Given to Gov. Connally Before His Speech to Law College,” n.d., The Philip G. Hoffman Papers, Box 38, Special Collections and Archives, University of Houston Libraries, Houston, TX.} Dr. F. M. Tiller, who served as the dean of the College of Engineering, stated, “[T]he establishment of NASA programs aided in the progress and development of the school by accelerating plans that were already underway.” Thus, the cooperative efforts assisted the University of Houston in improving its stature as an academic institution in the Southwest.\footnote{The Houston Post, 10 February 1963.}

With the continued expansion of population and industry in the Clear Lake area, the community required additional opportunities for higher education. By 1964, the University of Houston offered undergraduate and graduate courses ranging from elementary Russian, mathematics, physics, political science, and business administration to MSC employees in temporary classrooms at the NASA Center in Houston. However, Center Director Robert Gilruth, seeking more educational opportunities, urged the university to expand its operations in an effort to more effectively serve the interests of NASA employees, residents of the Clear Lake area,
and workers at the various aerospace companies. Additionally, he noted that the area’s large technical and scientific community made this need more imperative.46

On 25 November 1965 the Humble Oil and Refining Company donated 50 acres of land west of the MSC to the University of Houston to establish a branch campus.47 The president of the university, Dr. Philip G. Hoffman, who accepted the land gift for the board of regents, said, “[S]uch gifts would not only be acceptable, but welcome.”48 Following the announcement, Paul E. Purser, Gilruth’s executive assistant, stated that the establishment of a branch campus near the facility would provide a healthy and vigorous university climate in the area.49 After acquiring the necessary building funds from alumni gifts and private industries, construction began on the property in the early 1970s. Regular scheduled classes at the University of Houston at Clear Lake City began in September 1974 with a total enrollment of 1,069 students and a faculty comprised of 60 professors. Thus, the establishment of the branch campus contributed to the proper development of the state’s scientific and industrial strength.50

Additional Houston-area educational institutions benefited from specific NASA-related projects, such as the University of St. Thomas, which received funds from the Agency to conduct studies relating to the genetic effects of weightlessness; Baylor University College of Medicine, which was awarded a $258,000 space medicine grant to monitor astronauts’ brain waves and blood volume during human spaceflights; the University of Texas Graduate School of Biomedical Sciences, which was awarded a $65,000 grant to collect the astronauts’ clinical history data for medical researchers; the Texas Institute for Rehabilitation and Research, which was awarded a $171,183 grant for the development of computer technology for a medical data study relating to the Apollo program; and the Southwest Research Institute of Houston, which was the recipient of a $104,850 grant to assist the Agency in disseminating NASA technological developments to local businesses for

commercial applications.\textsuperscript{51} By the late 1960s, the total amount of Agency funds awarded to these respective educational facilities and research institutions was more than $3.6 million.\textsuperscript{52} These NASA grants differed from other research and development funds because they required highly paid and educated workers who demanded higher levels of education and residential accommodations. Houston and local officials responded to these demands by improving the area’s quality of education and infrastructure during the 1960s, which resulted in benefits for all members of the community.\textsuperscript{53}

The elementary and public schools in the Clear Lake area were also affected by the NASA Center because the children of MSC employees and contractors added to the schools’ population.\textsuperscript{54} During the 1950s school growth in the Clear Lake area ranged from 90 to 100 additional students each year. However, school growth since the 1960s represented an average increase of 1,021 pupils a year.\textsuperscript{55}

During the early 1960s the Clear Creek Independent School District, which was a consolidation of four school districts from the neighboring communities of Webster, Seabrook, Kemah, and League City, also faced a boom in its enrollment resulting from an influx of NASA families to the region. In the fall of 1961 the school district consisted of six schools and had a student population of 1,777 pupils. Within two years the Clear Creek School Board reported a 77 percent rise in its student enrollment. With the school district forced to accommodate an additional 1,046 students, the school board approved the construction of additional buildings and facilities to alleviate the tremendous growth problems, including an immediate four-classroom addition to the Webster Elementary School and a five-classroom addition to the Clear Creek Junior High School.\textsuperscript{56}

\textsuperscript{52} “NASA’s Prime Contractors & Prime Contract Awards as of December 31, 1967,” 31 December 1967, Robert C. Eckhardt Papers, Box 95-147/195, Center for American History, University of Texas at Austin, Austin, TX.

\textsuperscript{55} “Clear Creek Independent School District Enrollment Figures,” Clear Creek Independent School District, League City, TX; Lang, “Impact of MSC on the MSC Area.”

As children from families working at the NASA site and space-oriented industries in the area continued to overcrowd the Clear Creek Independent School District, the school board applied for federal aid to build additional campuses and expand existing facilities.\(^{57}\) In January 1965 the U.S. Office of Education awarded the school district a $185,000 grant to construct a new high school campus in League City. The funds were received under a law that grants aid to school districts affected by nearby government installations.\(^{58}\) During the next three years the school district used bond funds and federal grants to support the construction of three new elementary schools in El Lago, Clear Lake City, and League City, and a junior high school in Seabrook.\(^{59}\) As the Clear Creek Independent School District expanded to 10 schools and 8,627 pupils in less than five years, the district received $203,079 in federal funds to prepare for additional growth during the late 1960s.\(^{60}\)

From its inception, the MSC also developed a close relationship with the area’s school districts in an effort to heighten students’ interests in science and mathematics by disseminating knowledge about the space program to the local elementary and secondary schools.\(^{61}\) In 1964, Houston Independent School District teachers Erine Baker and Grant Morrison cooperated with Public Relations Specialist Eugene E. Horton, who served as the chief of the educational programs at the MSC, to develop materials designed to inform teachers and students about the Agency’s current activities. By 1966, the Houston Independent School District supplied elementary and secondary teachers throughout Texas with educational aids, including film clips, workbooks, and pictures related to the space program. The Houston Independent School District–NASA program demonstrated that educators could effectively work with highly technical information and design materials for classroom instruction. Additionally, the program established a permanent flow of information between Texas schools and the MSC.\(^{62}\)

The location of the MSC in Houston also changed Texas’s image because of the increased space research conducted in the state. As a result, Houstonians were accorded a worldwide identity as “Space City, U.S.A.” during the 1960s. Local company owners willingly accepted their new Space Age image by changing the names of their establishments to demonstrate their pride in the space program.

---

Businesses such as the Space City Bar-B-Q Restaurant, Apollo Broadcasting Company, Space Age Laminating Company, Apollo Paint Company, Astro Nut Company, Space City Hearing Aids Company, Astro Baby Sitters Agency, and the Apollo Restaurant and Lounge surrounded the NASA Center in the Clear Lake area. And naturally the space burger, which most Houstonians claimed “tasted out-of-this-world,” was served at the Apollo Restaurant and Lounge.63

Texas sports teams also adopted space-oriented names to pay tribute to the nation’s space pioneers. Despite the fact that many individuals believe the Houston Rockets basketball team was named after the launch vehicles that carried astronauts and satellites into space, the club was actually christened The Rockets when the organization was founded in San Diego, California, in 1967.64 However, the Houston Astros baseball team drew their club name from the astronauts.65 And in October 1965 Houston’s new professional ice hockey team was named the Apollos in honor of the lunar landing program.66

Local attractions in the Houston area also had Space Age names. For instance, Tranquility Park, which was a tribute to the Apollo 11 mission, was constructed in the city’s central business district. The enclosed multipurpose stadium where the Astros played was named the Astrodome, and adjacent to the sports complex was Astroworld, which was a recreational theme park that offered family entertainment.67

With Houston serving as the training center for America’s astronauts and as the control center for all human spaceflights, astronauts Michael Collins, Edwin E. “Buzz” Aldrin, Jr., and Neil A. Armstrong paid homage to the Lone Star State by flying a Texas flag aboard the command module during the Apollo 11 mission.68 This flight to the lunar surface was significant to Houstonians in another way because the first word spoken publicly by astronaut Neil Armstrong on the moon was the name of their city: “Houston . . . Tranquility Base here. The Eagle has landed.”69 In November 1969 astronaut Alan L. Bean, who was a Fort Worth native, also brought worldwide attention to the Lone Star State by carrying a Texas flag to the lunar

63. The Houston Post, 21 July 1969.
surface on the Apollo 12 mission. And although Apollo 16 astronauts Charles M. Duke, Jr., and John W. Young did not carry a Texas flag to the Moon, they did name one of the Moon’s craters “Lone Star” in honor of Texas.

**Conclusion**

Although the Agency did not utilize the MSC as a site to launch rockets into space, the installation did launch southeast Texas into an orbit of growth and prosperity as the federal complex brought international attention to the region and made Houston the focal point of the Space Age fever that was spreading throughout the nation. The NASA facility also served as a catalyst to the state’s economy and stimulated enormous development projects in the Clear Lake area. Thousands of new jobs were created in Houston as a result of the relocation of national aerospace firms to the region. Not only did these companies cause a new wave of industrialization in Texas, they also assisted in the diversification of state’s economy. The Center also enhanced the prestige and stature of the area’s academic institutions. More importantly, the federal complex contributed to the desegregation of Rice University, which recognized that it was necessary for a nationally competitive school to be racially integrated. As NASA placed Texas into orbit, the state entered a new era of technological, scientific, and economic progress during the late twentieth century.

---

Southern California, as any of its inhabitants will attest, is a rather particular—if not unique—place. Over the course of the twentieth century it evolved from irrigated agriculture, through an oil boom and the emergence of Hollywood, to its present status as a sprawling, high-tech nexus on the Pacific Rim. The central factor in this evolution, especially in the last half-century, has been the aerospace industry. The aerospace complex started with a few aircraft builders around World War I, vastly expanded in the mobilization for World War II, and then continued and broadened in the cold war to encompass a wide range of activities, including military and civilian aircraft, reconnaissance and communications satellites, and strategic missiles in addition to space exploration. By the 1980s about 40 percent of the American missiles and space business resided in southern California, as did about one-third of the aerospace engineers, and the industry as a whole there employed close to a half-million people. Southern California as we know it would not exist without aerospace, and, if one is looking for the societal impact of space exploration, one need look no further than the transformation of southern California in the twentieth century from sunbelt orange groves to high-tech metropolis.¹

Several thousand of these aerospace engineers worked at the Jet Propulsion Laboratory (JPL) in Pasadena. JPL worked with and spun off local aerospace firms, and experienced with them the ups and downs of federal support, but also competed with them in the local labor pool; it attracted publicity to the local community but also a backlash because of environmental pollution; and it intersected the Hollywood movie business in surprising ways. This paper examines a few of these evolving interactions to demonstrate how space programs both reflected and shaped southern California.

**Origins and the Aerospace Industry**

It was no accident that JPL sat at the geographic epicenter of the aerospace industry. Caltech’s aeronautics programs had close ties from the 1920s to nearby aircraft firms, and its research and graduates helped fuel the pre-World War II growth of the local aircraft industry. At the time, Caltech was already a center for science and engineering in the United States, fostered by philanthropic funding. This included money from the Guggenheim family for an aeronautics program, which in 1930 helped Caltech lure Theodore von Kármán, a leading authority on aerodynamics in Germany, to become director of the Guggenheim Aeronautical Laboratory at Caltech (GALCIT). In addition to promoting GALCIT’s collaboration with local aircraft firms on wind tunnel and other research programs, von Kármán supported research on rockets, which eventually led to Army support and, during World War II, the formal creation of JPL.²

The symbiosis continued in the cold war, and JPL’s evolution from rockets to spacecraft resonated with the diversification of local industry from aircraft to aerospace. Caltech continued to manage JPL, first under an Army contract and then under NASA. JPL differs from the other NASA Centers in its association with a university—one well-connected with local aerospace industry. Caltech (through GALCIT and JPL) provided to the industry both research underpinning technological advances and also a steady supply of science and engineering graduates, such as Simon Ramo and Dean Wooldridge—the R and W in TRW. These links may be measured by the many aerospace executives on Caltech’s board of trustees, several of whom also served on a special committee overseeing JPL and hence injected industrial perspectives. Although Caltech and JPL had exceptionally well-developed connections, they were by no means unique in southern California: Convair engineers helped establish the science and engineering departments at the University of California at San Diego; Boeing similarly cultivated Cal-State Long

---

Beach as a labor source; and Hughes supported the engineering program at the University of Southern California. JPL also intersected local industry as a competitor in the labor market. JPL managers viewed southern California as a more competitive labor market than that of other NASA Centers, since JPL engineers could jump to any number of industry firms without the hassle of relocating; lab managers consistently worried about losing top talent. As JPL grew to be the largest employer in Pasadena, its evolving mission shaped its ability to recruit and retain staff. After the lab shifted to NASA it gradually relinquished secret defense work, which made it particularly attractive to aerospace engineers who did not want to work in a classified environment. Since many (if not most) local aerospace jobs required a security clearance, this could provide a substantial recruiting inducement, not only for those morally opposed to military work but also those—such as homosexuals—who feared an intrusive clearance process. This became an issue when JPL resumed substantial military work in the 1980s, amid a general remilitarization of the space program. JPL more generally capitalized (with the rest of local industry) on the southern California climate as a recruiting tool. A number of JPL staff went job hunting in southern California at least in part because of the weather, especially those who started in the early years of the 1950s and 1960s, and even more especially those from colder climes. As one engineer put it, “The Chamber of Commerce sent me this booklet that showed beautiful mountains, no smog, snow on the top, and orange trees,” and that was all the inducement necessary to head west.

JPL also reflected the ethnic composition of the local labor pool. Like the rest of NASA, lab staff was very largely white and male, following the national demographic of science and engineering disciplines, but JPL generally had almost twice the proportion of minorities on the staff than did NASA, and Asian ethnic groups made up the largest fraction of minorities, followed by Hispanics and African

---

3. On Convair engineers and San Diego colleges: Marvin Stern, interview by Finn Aaserud, 1 May 1987, American Institute of Physics.

Americans. Affirmative action policies and the increasing number of minority scientists and engineers nationwide almost doubled minority representation from the 1970s to the 1990s (from 13 percent in 1976 to 25 percent in 1994), although upper management remained a mostly white male province. Hispanics and especially Asian Americans continued to constitute most of the minorities (8 percent and 11 percent, respectively), in particular among scientists and engineers (14 percent Asian), so that whites, Asians, and Hispanics held better views of JPL's diversity than did African Americans.

JPL’s connections to local industry extended to spinoffs—from major defense contractor Aerojet, spun off during World War II, to more recent smaller startups such as ViaSpace and Photobit—and of course to local contractors. Many local firms made their living in part off JPL contracts, in what economists would explain as a high-tech, post-Fordist example of earlier concentrations of craft industry (such as Lyon silks or Alsatian calico), where mutually independent producers capitalize on a common labor market and on a network of suppliers and services. About one-third of JPL’s subcontracting currently goes to southern California firms, and even for contracts that went to other aerospace hotbeds, such as to Lockheed Martin in Colorado, some of the subcontracts for those programs ended up in southern California as well.

On the other hand, big aerospace firms could view JPL projects as contributing a mere pittance to company balance sheets. For groups such as the Hughes Space Division, which might have sales of several hundred million dollars a year, a JPL contract for $50 million or $100 million spread out over several years provided a very small fraction of business. That did not keep them from competing for contracts or from complaining that JPL kept work in-house instead of contracting it to industry. As firms such as TRW and Hughes developed extensive satellite expertise (most of it through spacecraft for military reconnaissance and commercial communications), JPL faced competition from aerospace firms both near and distant, and NASA and Congress consistently pressured the lab to farm out more work. Periodic downturns in civil and military space spending increased the competition from aerospace firms. The end of the cold war, in particular, marked a turning point for JPL, the aerospace industry, and southern California itself. JPL contemplated

11. Westwick, Into the Black.
the grim prospect that the lab itself might shut down and, as the aerospace industry hemorrhaged jobs, Caltech’s president declared that “This is a time of triage—[the] only question is what is going to die.” JPL’s response, known as the “employee displacement strategy” or “right-sizing”—or, more bluntly, downsizing—produced staff cuts of 30 percent over the next several years. Though not as deep as the cuts suffered by the aerospace business in general, they represented and contributed to the general malaise of the early 1990s in southern California.

JPL survived because it found new justifications (besides the pork-barrel political support it received as a large local enterprise.) One response to the end of the cold war was to celebrate the triumph of the private sector and, as military threats receded, the federal government shifted emphasis to economic concerns. Clinton’s presidential campaign catchphrase of 1992—“It’s the economy, stupid”—infected NASA and JPL, which channeled the entrepreneurial buzz into efforts to transfer space technologies to the civilian economy. The usual approach involved licensing and patents, but JPL also spun off people and their ideas in small startup companies. Caltech encouraged the spinoffs by providing startup capital through a “grubstake” grant program, with an equity stake retained by the university. The startups also capitalized, literally, on the thriving venture capital business in California in the 1990s, which quickly learned to target the people and ideas emerging from JPL.

These spinoff companies supported new justifications for the space program based on high technology for economic growth. The clustering of offshoots such as Photobit and ViaSpace around the lab helped the local economy rebound from aerospace cutbacks, but they also demonstrated some resistance to the commercial spirit at JPL. Lab managers worried that engineers constantly on the lookout for business opportunities might not stay focused on the job of building spacecraft. Lab managers also feared the loss of key staff. In 1998, for example, Carl Kukkonen, the architect of JPL’s microelectronics program, left to start ViaSpace, and he sought to bring a number of JPL staff with him. Caltech agreed but asked that he keep his recruiting within reasonable bounds—as Kukkonen put it, “retail rather than wholesale.” Lab managers also anticipated that NASA auditors, despite the Bayh-Dole Act promoting technology transfer, would charge that individuals were profiting from government-funded research. In some cases the Caltech president and trustees had to intervene to overcome JPL’s and NASA’s concern about the private-public divide, which continued to dampen the embrace of entrepreneurialism.

JPL has always interacted with the local geography and environment. The lab itself sits in the Arroyo Seco, a dry wash three miles above the Rose Bowl in Pasadena. The isolated spot was chosen for initial rocket tests in the 1930s, not so much for safety as because no campus facilities were available. The wisdom of using a remote site was confirmed, however, when subsequent tests on the Caltech campus misfired, one explosively. When the Army Air Corps then stepped up wartime funding, the rocketeers returned to the Arroyo, but only after the city of Pasadena, protecting the interests of nearby high-end homeowners, insisted that the site would serve only for the duration of the war. By war’s end, the growth of apparently permanent structures alarmed city managers, but when the Army threatened to invoke eminent domain the city gave in and signed a long-term lease. JPL remains in the Arroyo today, although it had to seek a more remote site for rocket tests in the Mojave desert near Edwards Air Force Base. The California high desert provided isolation of a different sort necessary for deep-space tracking and communication, removed from radio noise, and the cornerstone of what would become the Deep Space Network was laid in the late 1950s on a dry lake bed at Goldstone in the Mojave.

Despite the rocky start with the city of Pasadena, for the local community JPL largely represented a boon. The lab and Caltech came to enjoy substantial influence with local media and city government, by virtue of their size and prestige—enough to squash the occasional protest from neighbors over the construction of new buildings. With more than 4,000 staff by the mid-1970s, JPL at that time was the largest employer in Pasadena. This statistic relied on the fact that JPL staff were Caltech employees; JPL itself was not located in Pasadena. It lay outside the city limits on land annexed by the neighboring town of La Cañada-Flintridge when it incorporated in 1976. After much squabbling between rival city boosters, including the Pasadena city manager’s declaration that “to see it end up in some other corporate limits would be like losing the Rose Bowl,” the U.S. Postal Service left the decision up to the lab and JPL chose Pasadena. La Cañada-Flintridge residents were still stewing about the episode 20 years later.

18. JPL Institutional Background and Overview, 3 October 1975 (JPL 142, 27/483).
Pasadena city leaders soon had cause to regret JPL’s proximity. Increasing public sensitivity in the United States to environmental pollution resulted, among other things, in the Safe Drinking Water Act of 1976 and testing of water supplies. In 1980 state health authorities began testing water wells in Pasadena and found a number of them contaminated with toxic carcinogens, including four wells in the Arroyo Seco east of JPL. The lab had developed formal control of hazardous waste in the early 1960s; before that, JPL had used cesspools, dumping pits, and an incinerator to dispose of wastes at the east end of the lab.20

Pasadena officials assumed the contamination came from JPL’s early rocket research. The lab initially denied blame, noting that the contaminants—trichloroethylene, carbon tetrachloride, and tetrachlorethylene—were common industrial solvents; 30 other wells throughout the San Gabriel Valley had also turned up excessive traces. JPL nevertheless agreed in 1985 to fund jointly with Pasadena an engineering study, in the spirit of a “good neighbor” and without admitting liability. An outside consultant subsequently concluded that JPL was the “most probable source” and recommended construction of a water treatment plant.21 NASA agreed to pay for the plant, built in 1990 at a cost of $1.3 million, and JPL planned to commit about $1 million a year for several years for cleaning up the contamination. In 1992 JPL was named a “Superfund” site, one of more than 1,000 polluted places identified by the federal government for environmental remediation.22

In this respect JPL differed little from many other aerospace sites, not to mention nuclear labs and other enterprises, that had raced to beat the Soviets in the cold war—at a time of more cavalier attitudes toward waste disposal and the environment—and then faced the consequences decades later. The concentration of aerospace business in southern California, however, has made the cold war environmental legacy more acute there. This, too, is one of the societal impacts of space exploration.

Environmental liability would be a major issue in contract negotiations with NASA. Caltech feared exposing its endowment to lawsuits, while NASA found itself paying for damage likely incurred under the previous Army contract.23 This was not just splitting hairs: JPL was shortly slapped with a lawsuit alleging that pollution caused the death of one local woman and Hodgkin’s disease in two others;

31 other local residents petitioned to join the case. A groundwater study by the federal Health and Human Services Department in 1998 found no current threat and judged past hazards “unlikely,” but JPL continued to grapple with lawsuits into the new century.24

JPL’s response to the groundwater problem is instructive. Despite the lawsuits, JPL avoided the much more active environmental controversies that plagued some other government labs. Brookhaven National Lab, to take one example, encountered an uproar after revelations in the 1990s that a plume of groundwater near a nuclear reactor contained tritium. Hundreds of community activists packed public hearings and vented their anger. Brookhaven scientists could not understand the fuss over what they saw as a negligible hazard, but local residents resented what they viewed as evasions and patronizing reassurances based on statistical risk analysis. Brookhaven learned a hard lesson in community relations: the lab director was effectively pressured out of his job and the contractor, which had run Brookhaven for 50 years, saw its contract summarily terminated by the Department of Energy in 1997.25

The JPL case differed in that it dealt with common industrial chemicals, whereas Brookhaven and other nuclear labs involved radioactivity, with its popular associations of danger and secrecy.26 Another prime difference from labs such as Brookhaven was that JPL, like NASA as a whole, had a finely tuned public relations organization and decades of experience with operating in the media glare, including highly exposed failures. Brookhaven scientists, by contrast, admitted their lack of public relations expertise. At the outset of the controversy at JPL, lab managers emphasized to staff that any public comments “will not underestimate the important nature of the problem. For example, we will not cite statistics in an effort to demonstrate that chances of getting cancer from Pasadena drinking water are low.”27 Another internal memo stressed that JPL and NASA should “maintain a positive, cooperative attitude in dealing with the city. The contribution of a substantial part of the construction cost of a treatment plant is preferable to the consequences of sensational adverse

press coverage of the situation.” JPL’s public relations experience, well-honed by the civil space program, helped it largely avoid the antagonistic community reaction that could characterize environmental cleanup at other cold war labs.

**Hooray for Hollywood**

The lab also forged links with another prominent local industry, namely, show business. Hollywood knows a spectacle when it sees one, and celebrities often descended on JPL for planetary encounters. This included not only actors and actresses, but also writers with studio connections—especially local science-fiction writers, who had a natural interest in JPL’s work. In the lab’s earliest days, two of its founders, Frank Malina and Jack Parsons, tried to sell a story about their rocket group to Metro-Goldwyn-Mayer to raise money for their research; Parsons later hobnobbed with L. Ron Hubbard and Robert Heinlein and lost his life in an explosion while working on pyrotechnic special effects for Hollywood.

29. By the 1970s sci-fi writers were a strong presence around JPL for planetary encounters, including such luminaries as Arthur C. Clarke, Ray Bradbury, and Heinlein. As with aerospace, Caltech helped nourish JPL’s Hollywood ties with its own elite connections, including trustees (and JPL overseers) such as mogul Lew Wasserman.

Movie trends revealed Hollywood’s periodic fascination with space exploration, such as in the late 1970s, when the first *Star Trek* movie featured a mysterious, nearly sentient object known as V-GER. The trend revived in the late 1990s, when the discovery of a Martian meteorite with possible life-forms, the Shoemaker-Levy comet impact on Jupiter, and Mars Pathfinder were followed by blockbuster movies including *Deep Impact* and *Armageddon*, about meteor impacts on Earth, and *Mission to Mars* and *Red Planet*, about mysterious life-forms on Mars, not to mention several new installments of the *Star Wars* saga. JPL’s executive council in 1999 noted the surprising interest in “space movies and the merging of entertainment and realities.”

The merging included a new mission, approved that year, which planned to fire a 1,000-lb (500-kg) projectile into the comet P/Tempel-1 and observe the resultant crater; JPL’s project manager had to insist that the mission’s name, Deep Impact, was in fact selected prior to the movie.

There are more substantial connections between JPL and the movie business in the lab’s technical program. In the early 1960s JPL engineers had pioneered

the use of digital image processing, first to clean up pictures returned from the Ranger missions to the Moon, and later on other planetary spacecraft images. The first techniques corrected distortions and removed signal noise, such as a particular frequency superimposed on an image by vibration of the camera, and grew to encompass algorithms for contrast enhancement, cartographic projection, motion compensation, and so on (in short, many of the techniques now available through such software packages as Photoshop).31 By the mid-1970s, what was known as the Image Processing Laboratory at JPL had perhaps the most advanced capability in the country.

Meanwhile, JPL had also supported important early work on computer animation. In the late 1970s JPL hired a young programmer from Utah named James Blinn, a student of Ivan Sutherland (who was now at Caltech). Blinn was making a name as a guru of computer graphics; Sutherland, himself no slouch, would say, “There are only a dozen great people in computer graphics, and Jim Blinn is six of them.” Blinn went to work with Charles Kohlhase on the Voyager project, generating three-dimensional animations simulating Voyager’s flight past Saturn, at each point calculating the relative appearance of planets and stars. The three-dimensional (3-D) movies—in which the viewer rode along with Voyager as the spacecraft swooped over Saturn’s rings and satellites—proved a hit with TV news editors and viewers. Similar graphics sequences from Blinn enlivened the Cosmos television series of Carl Sagan.32

Although Blinn was not a part of the Image Processing Lab, his computer animations for Voyager and Cosmos used similar techniques, such as reconstructing viewing geometries and surface reflectance.33 The Image Processing Lab had also produced its own motion pictures by combining still photos, such as those from the Ranger and Mariner spacecraft. Around the time of Blinn’s work on Voyager, Kevin Hussey was doing some crude 3-D animation for atmospheric scientists, including modeling the smog distribution in the Los Angeles basin. Hussey heard about Blinn’s work and approached him for help, but lacked the budget to hire him. So Hussey used in-house code written by Mike Kobrick in the Image Processing Lab and, with the help of a young programmer named Bob Mortensen, tweaked it for his purposes. The result, in 1987, was L.A. the Movie, which projected topographic data from Landsat to simulate the 3-D view from an aircraft swooping through the Los Angeles basin. By that time Hussey’s group had grown from 2 to 14 and

had formally organized as the Digital Image Animation Lab (DIAL), alongside and overlapping the original Image Processing Lab.\(^{34}\)

Blinn had meanwhile gotten several offers from the movie business and in 1981 accepted one from George Lucas to establish a special effects studio for *The Empire Strikes Back*, the first *Star Wars* sequel. At the Lucas studio Blinn teamed up with Alvy Ray Smith, who had himself worked briefly with Blinn at JPL. Blinn’s work at JPL had already had some influence: the sequence that persuaded Lucas of the potential of computer graphics was developed by Smith’s team for *Start Trek II: The Wrath of Khan*, which showed the view from a spacecraft flying past a dead, Moon-like planet which then is transformed by a fiery cataclysm into an Earth-like environment. In creating this “Genesis” shot, Smith declared, he “was still under the influence of Blinn’s Voyager flybys of the planets at the Jet Propulsion Laboratory.” After joining Smith for a stint at Lucasfilm, Blinn returned to the Caltech campus and later became a “graphics fellow” at Microsoft; Smith would go on to help found Pixar.\(^{35}\)

Hussey had also intersected Hollywood through work on digital color correcting, starting with a CBS television special on the *Mona Lisa* and then on color correction of old *Star Trek* backgrounds. He had then helped William Shatner with a zoom shot from the galaxy down to Yosemite Valley for another of the *Star Trek* movies and digitally erased telephone wires from the Egyptian skyline for *Raiders of the Lost Ark*. He had also developed a technique to interpolate between still images, from work for ocean scientists creating continuous animation of ocean circulation from satellite images taken 12 hours apart; he applied this on work for Whitney/Demos Productions, one of the leading graphics studios, to morph images into one another—an early example of the technique popularized by *Terminator 2* and Michael Jackson’s *Black and White* video in 1992. Hussey soon had a stream of movie producers coming through his door for what he called “demo after demo” of VICAR (Video Image Communication and Retrieval) and other JPL digital processing software.\(^{36}\)

Hollywood was hooked, and in the mid to late 1980s began to pour money into digital techniques, aided by the emergence of commercial software packages such as Photoshop. Disney soon hired away Hussey and several others from the DIAL to help build its own digital animation studio, including work with Pixar’s movies. By the mid-1990s Hollywood’s vastly greater resources allowed it to outstrip the

---

capabilities at JPL—even though most of DIAL’s funding came from outside NASA, with IMAX as the largest sponsor. As a result, the influence began to run mostly in the opposite direction, from Hollywood to JPL. Hussey himself returned to JPL after several years at Disney, bringing with him the latest from Hollywood studios. These included 3-D gaming techniques, which JPL applied not only for outreach efforts (allowing kids to play online games of planetary exploration), but also to help mission managers visualize what their spacecraft are doing in space, by transforming raw telemetry into real-time animations. Such techniques have closed the loop from JPL to Hollywood, and from popular interest to technical capability.

**Conclusion**

JPL’s impact on southern California has ranged from the local aerospace industry and labor pool, to its environmental legacy, to Hollywood studios. But the influence throughout has run both ways. We might ask not only about the societal impact of space programs, but also whether southern California left a particular stamp on the enterprise of space exploration. What were the consequences of the concentration of aerospace for the space program? California historian Kevin Starr has long described the state as a land of dreamers; did the blue-sky California environment encourage dreams of soaring beyond the sky, in the attitude captured by a California-ism from that other local industry, “imagineering”? Or did California’s recreation and leisure culture—all that sun and sand and surf—instead distract space engineers from their work, as it can also distract space historians?

Or could one go even further and ask whether there is a distinctive southern California type of spacecraft. Perhaps not, although those Mars Rover airbags look suspiciously like beach balls bouncing across the sand. But one could speculate that southern California attracted or nurtured a particular mindset or sensibility, one attuned to the imaginative possibilities and the public appeal of spaceflight. JPL managers identified two general categories of staff: the benchtop engineers building hardware (or software), and the mission designers. It was the mission designers who were perhaps more susceptible to the context. Consider Bruce Murray, for example, who as JPL director would emphasize missions with popular appeal over strictly scientific goals. In the 1970s Murray released the “purple pigeons,” a group of proposed missions with razzle-dazzle for the public (such as a solar sail to Halley’s

comet); he would continue to push such flights of fancy as an interstellar probe, Mars airplanes, and Venus submarines in the planetary program and in the civil space program in general. Such attitudes were not confined to southern California—but it might be no accident that Murray had grown up just across town in Santa Monica. (It might also be no accident that he has been the only one to wear shorts and sandals behind the JPL Director’s desk.)

One might speculate further that JPL, by virtue of its location, attracted more than the usual share of Bruce Murrays. And an attitude like Murray’s did in fact influence spacecraft design. Emphasizing popular appeal often meant imaging—that is, spacecraft that returned pictures instead of just reams of numerical data. And imaging cameras in turn meant three-axis-stabilized spacecraft instead of the spin-stabilized spacecraft preferred for particles-and-field experiments. This preference shows up in JPL’s long tradition of three-axis-stabilized craft. (For the Galileo spacecraft, JPL review boards and Murray himself recommended dumping a complicated spun/despun design, which combined a spin-stabilized section with a three-axis-stabilized platform, for a straight three-axis spacecraft.) A 1987 proposal from the nearby Planetary Society for a robotic Mars spacecraft captured the people-pleasing sensibility and the sense that planetary missions were all about entertaining the public. The proposal stressed that “Science should be given a low priority on this mission, if it is given any direct participation at all . . . . Imaging, imaging, and more imaging is the name of the game . . . . The aim here is to obtain images that are shameless crowd-pleasers and show Mars from a human perspective. If that’s not good science, well then tough.” A Hollywood flack couldn’t have said it any better. If one considers that the entertainment industry passed aerospace in 1995 as the main employer in California, it may indeed be appropriate to view JPL itself as a subset of the entertainment business.

Section VI

Spaceflight, Culture and Ideology

———
The ideas of frontier pioneering, continual progress, manifest destiny, free enterprise, and rugged individualism have been prominent in the American national narrative, which has constructed and maintained an ideology of “Americanism”—what it means to be American, and what America is meant to be and do. In exploring the history of U.S. spaceflight, it is useful to consider how U.S. space advocacy movements and initiatives have interpreted and deployed the values and beliefs sustained by this national narrative. The aim here is to illuminate the role and function of ideology and advocacy in the history of spaceflight by examining the rhetoric of spaceflight advocacy. Starting from the premise that spaceflight has played a role in the American national narrative and that this national narrative has played a role in the history of spaceflight, this paper examines the relationship between spaceflight and this narrative.

Examining the history of spaceflight advocacy reveals an ideology of spaceflight that draws deeply on a durable American cultural narrative—a national mythology—of frontier pioneering, continual progress, manifest destiny, free enterprise, rugged individualism, and a right to life without limits. This ideology rests on a number of assumptions, or beliefs, about the role of the United States in the global community, the American national character, and the “right” form of political economy. According to this ideology, the United States is and must remain “Number One” in the world community, playing the role of political, economic, scientific, technological, and moral leader. That is, the United States is and must

---

1. In this paper, “spaceflight” generally refers to human spaceflight but does not exclude robotic spaceflight. The terms “spaceflight” and “space exploration” are interchangeable in this paper, even though they can convey different meanings in different contexts. General overviews of the history of space advocacy may be found in Tom D. Crouch, *Aiming for the Stars: The Dreamers and Doers of the Space Age* (Washington, DC: Smithsonian Institution Press, 1999); Howard E. McCurdy, *Space and the American Imagination* (Washington, DC: Smithsonian Institution Press, 1997).
be exceptional. This ideology constructs Americans as independent, pioneering, resourceful, inventive, and exceptional, and it establishes that liberal democracy and free-market capitalism (or capitalist democracy) constitute the only viable form of political economy. The rhetoric of space advocacy exalts those enduring American values of pioneering, progress, enterprise, freedom, and rugged individualism, and it advances the cause of capitalist democracy.

Delving into the language or rhetoric of spaceflight is a productive way of exploring the meanings and motives that are embedded in and conveyed by the ideology and advocacy of spaceflight—the cultural narrative of pioneering the space frontier. According to rhetorical critic Thomas Lessl, rhetorical analysis can shed some light on

... [T]he processes of communication that underpin decision making in free societies ... Judgments on matters of public policy take their cues from rhetoric, and so an understanding of any society’s rhetoric will tell us a lot about its ideas, beliefs, laws, customs and assumptions—especially how and why such social features came into being.3

To begin this analysis, some definition of key concepts is warranted, starting with culture and communication. Anthropologist Clifford Geertz’s definition of culture is operative in this analysis:

[Culture is an] historically transmitted pattern of meanings embedded in symbols, a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate and develop their knowledge about and attitudes toward life. [It is a context within which social action can be] intelligibly—that is, thickly—described.4

Building on Geertz’s conception, communication theorist James Carey has characterized culture as a predominantly rhetorical construction, “a set of practices, a mode of human activity, a process whereby reality is created, maintained and transformed,” primarily by means of communication.5 Social norms can be constructed, perpetuated, and resisted—and ideologies can be propagated—“through

2. For an exposition of this idea, see, for example, Francis Fukuyama, The End of History and the Last Man (New York: Free Press, 1992).
Space History from the Bottom Up: Using Social History to Interpret the Societal Impact of Spaceflight

ritualized communication practices.”6 When advocates speak of advancing scientific and technological progress by exploring and exploiting the space frontier, they are performing ritual incantations of a national myth, repeating a cultural narrative that affirms what America and Americans are like and are meant to do. For the purposes of this analysis, communication is a ritual, culture is communication, and communication is culture.

Standard definitions of ideology and advocacy are operational here. An ideology is a belief system (personal, political, social, cultural). Advocacy is the act of arguing in favor of a cause, idea, or policy.

**Ideological Bedrock**

The concepts of “progress” and the “frontier” require more extensive explication, as they are bedrock elements of the ideology of spaceflight. The root of “progress” is the Latin word meaning “to go forward.” J. B. Bury said progress is movement “in a desirable direction”—but he also noted that “it cannot be proved that the unknown destination towards which man is advancing is desirable.”7 In their histories of the idea of progress, both Bury and Robert Nisbet called progress a dogma. Christopher Lasch contrasted the premodern, Christian idea of progress—“the promise of a secular utopia that would bring history to a happy ending”—with the modern idea representing “the promise of steady improvement with no foreseeable ending.”8 Bury identified progress as an idea originating in the modern era, whereas Nisbet traced its roots to ancient Greek and Roman philosophy, and he documented how it evolved to take on the qualities of destiny and “historical necessity.”9 Nisbet declared progress the most important idea in modern Western history. This modern idea of necessary and inevitable forward movement is deeply embedded in the cultural narrative of U.S. spaceflight.

The idea of progress became the dominant idea in Western thinking in the period 1850–1900, according to Nisbet, serving as “the developmental context for other [key] ideas” such as freedom.10 Nisbet credited nineteenth-century natural philosopher Herbert Spencer with melding the ideas of progress and freedom, in

---

10. Ibid., p. 179.
declarations of “the rights of life and personal liberty,” “the right to use the Earth,” “the right of property,” and “the right to ignore the state.” Spencer’s classical liberal thinking is noticeable in the rhetoric of space advocacy.

From the seventeenth through the twentieth century, as Walter McDougall wrote, the Western scientific worldview—its own cultural narrative of sorts—“elevated technological progress . . . to the level of moral imperative.” Science and technology became the means of American progress, and conquest and exploitation became the morally imperative method. Ultimately, progress came to be thought of as the accumulation of material wealth. Robert Wright has said the idea of progress is “a Victorian ideal” of moral advancement that has evolved into an ideal of material improvement. This belief in progress performs the mythic function of providing moral justification for material accumulation. Along those same lines, Kirkpatrick Sale has asserted that the contemporary “myth” of progress advances “the propaganda of capitalism,” the idea of continual human improvement by means of resource exploitation and material accumulation.

Author Ishmael Reed has made the link between progress and spaceflight in an essay called “Progress: A Faustian Bargain”:

> In order to justify its programs, NASA, in its brochures, describes the Earth as a dying planet, a fact which for them justifies colonizing the universe . . . . You can understand why, in many science fiction movies, the goal of the invaders is to destroy this planet, lest this progress be extended to their neighborhoods.

Historically and presently, the rhetoric of space advocacy advances a conception of outer space as a place of wide-open spaces and limitless resources—a space frontier. The metaphor of the frontier, with its associated images of pioneering, homesteading, claim-staking, and taming, has been persistent in American history. In the rhetoric of spaceflight advocacy, the idea of the frontier is a dominant metaphor. It is worth noting that the root of the word “frontier” is the Old French word for “front.” In the English language, that word “front” conveys a complex of meanings, ranging from the most common definition—the part of anything that faces forward—to the definition that probably comes closest to the meaning of “front” in “frontier”: an area of activity, conflict, or competition. A common military definition of “front” is also tied up in the meaning of “frontier,” that is, the area of contact between opposing

11. Ibid., p. 229.
combat forces. Other meanings of “front” that should be considered in assessing the meaning of the frontier metaphor are: a façade; a position of leadership or authority; and a person or thing that serves as a cover for secret, disreputable, or illegal activity. What meanings are advocates intending to convey, and what meanings are they in fact conveying, when they talk about the space frontier?16

Historian Frederick Jackson Turner’s century-old essay, “The Significance of the Frontier in American History,” is perhaps the best-known articulation of the frontier metaphor.17 It is a powerful and evocative piece of writing. In making the case for spaceflight, advocates continue to cite, directly or indirectly, Turner’s frontier thesis and the related, potentially dangerous, idea of manifest destiny, seemingly oblivious to a changed cultural context and critiques of Turner’s thinking.

As Wright and Sale did with progress, Richard Slotkin, in his trilogy of books about the history of the American West, has deemed the idea of the frontier a myth—a myth in which the United States is “a wide-open land of unlimited opportunity for the strong, ambitious self-reliant individual to thrust his way to the top.”18 Patricia Nelson Limerick has pointed out that space advocates cling to the frontier metaphor, conceiving “American history [as] a straight line, a vector of inevitability and manifest destiny linking the westward expansion of Anglo-Americans directly to the exploration and colonization of space.” Limerick has warned that in abusing this metaphor, “[S]pace advocates have built their plans for the future on the foundation of a deeply flawed understanding of the past, [and] the blinders worn to screen the past have proven to be just as effective at distorting the view of the future.”19

**The Cultural Narrative of Spaceflight**

According to rhetorical critic Janice Hocker Rushing, “Rhetorical narratives are discourses which explicitly or implicitly advocate moral choices.” Rushing has said that the meanings of “definitional [American] cultural myths,” such as the myths of the Western frontier and the space frontier, are a source of identity and “moral vision.” Rushing noted that the United States “has drawn upon the frontier

---

16. All definitions were obtained from http://www.dictionary.com (accessed June–July 2006).
for its mythic identity,”20 or moral imperative, as McDougall called it. In this mythic universe, the cultural role of the explorer—the frontier conqueror, as it were—is, as Stephen Pyne has said, to serve as “a moral missionary, telling others and his sustaining civilization who they are and how they ought to behave.”21

From the start, advocates constructed a narrative of spaceflight that made it a necessary, even biologically driven, enterprise. But, as Pyne has pointed out, spaceflight and other modes of exploration are not in our genes but in our culture. “Exploration cannot be extracted from the historical and cultural context within which it occurs.” It is “a specific invention of specific civilizations conducted at specific historical times.” Advocates of U.S. spaceflight have created their own frontier mythology, as Limerick has noted, expanding the story of Western American settlement to encompass space exploration. And problems have ensued because, as Pyne has said, “discovery among the planets is qualitatively different from the discovery of continents and seas.”22

THE HISTORY OF ROCKET-MEN: SPACEFLIGHT AS A BELIEF SYSTEM

The U.S. and European rocket societies of the 1920s, 1930s, and 1940s were the world’s first spaceflight advocacy groups. German advocate Willy Ley documented the exploits of these groups, the titles of his books articulating the ideology of spaceflight: Engineers’ Dreams (1954), Across the Space Frontier (1952, with Wernher von Braun, Fred Whipple, and others), The Conquest of Space (1949), Harnessing Space (1963), and others.23 Frank Winter called these early advocates—including Konstantin Tsiolkovsky, Robert Goddard, and Wernher von Braun—“pioneers.”24 According to William E. Burrows, the Russian Tsiolkovsky advocated “controlling all of nature—the entire universe,” toward enabling human colonization. Tsiolkovsky was greatly influenced by the late nineteenth-century Russian mystic philosopher Nikolai Fyodorov, who “believed that Earth is not humanity’s natural home” and that humanity was intended to live in the cosmos. U.S. rocket developer Goddard

22. Ibid., pp. 14, 18.
Space History from the Bottom Up: Using Social History to Interpret the Societal Impact of Spaceflight

reportedly shared this belief. An inheritor of this legacy, Wernher von Braun said the aim of the German rocketeers was “to open the planetary world to mankind.” In 1930, U.S. science-fiction writers and fans formed the American Interplanetary Society to advocate spaceflight, and in 1934 this group became the American Rocket Society. These early American advocates engaged in “relentless . . . publicizing . . . via newspapers, magazine articles, lectures, demonstrations, exhibits, radio talks, and films” to proselytize for spaceflight.

In July 1958, physicist Freeman Dyson made his contribution to the advocacy campaign for spaceflight with “A Space Traveler’s Manifesto”:

From my childhood it has been my conviction that men would reach the planets in my lifetime . . . [T]his conviction . . . rests on two beliefs, one scientific and one political: (1) There are more things in heaven and earth than are dreamed of in our present-day science. And we shall only find out what they are if we go out and look for them. (2) It is in the long run essential to the growth of any new and high civilization that small groups of people can escape from their neighbors and from their governments, to go and live as they please in the wilderness.

As visions of spaceflight advanced toward reality, the rhetoric of spaceflight advocacy continued to promote conquest of the space frontier. Science-fiction author Olaf Stapledon wrote in 1948 for the Journal of the British Interplanetary Society that humankind should colonize other planets to exploit their resources for Earth’s benefit and to “increase man’s power over the environment . . . The itch to leave a mark is quite wholesome, on condition that, even if it does not actually serve some higher aim, at least it does not positively hinder proper development.” Pope Pius XII reportedly told the International Astronautical Federation in 1957, “God who has planted within the heart of man the insatiable desire for knowledge . . . did

26. Wernher von Braun, “German Rocketry,” in The Coming of the Space Age, ed. Arthur C. Clarke (New York: Meredith Press, 1967), pp. 33–55, quote from p. 55. “There was much regret among us” at Peenemünde, von Braun wrote in this essay, “that the A-4 [a.k.a. the V-2], conceived as it was as a first step to interplanetary rocketry, had joined in the bloody business of war.” (p. 54)
27. Winter, Prelude to the Space Age, p. 14. Successors to the American Rocket Society include the American Astronautical Society and the American Institute of Aeronautics and Astronautics, now representing professionals rather than amateurs and fans, and more prone to tend to matters of government policy and spending while less prone (though not averse) to proselytizing for spaceflight.
not intend to put a limit to man's endeavor.”30 Also in 1957, rocketeer Krafft Ehricke asserted that “the entire solar system, and as much of the universe as he can reach” are humankind’s rightful domain: “[B]y expanding through the universe, man fulfills his destiny as an element of life, endowed with the power of reason and the wisdom of . . . moral law.”31 In 1964, space advocate Charles Sheldon wrote that “[M]ankind is destined to step beyond his earthly bonds just as his ancestors once crawled out of the seas.” By “colonizing new worlds . . . spread[ing] into new places,” Sheldon wrote, “the race will survive.”32

The rocket-men of earlier decades and the geopolitics of the cold war propelled the U.S. space program into being and kept it going through the Apollo era. In that era, spaceflight advocacy came from two sources, according to William Burrows: political pragmatists and a “hard core of implacable dreamers; the unabashed zealots who shared a religious conviction that it was their race’s destiny to explore other worlds and then start colonies on them.”33

From the end of the Apollo era to the present, the ideology of spaceflight and the rhetoric of spaceflight advocacy have been sustained in public discourse in large part by the so-called grassroots space advocacy groups, such as the National Space Institute and the L5 Society and its successor, the National Space Society; the Space Studies Institute; and the Space Frontier Foundation. Wernher von Braun founded the National Space Institute (NSI) in 1974 to help cultivate public support for the U.S. space program in the post-Apollo era. The L5 Society was founded in 1975 by advocates Carolyn and Keith Henson to promote space colonization, as espoused by Princeton University physics professor Gerard K. O’Neill, who published his first paper on the subject, “The Colonization of Space,” in the September 1974 issue of Physics Today. Today’s National Space Society (NSS) is the product of a merger of the L5 Society and the National Space Institute in 1987. (The NSI was originally named the National Space Association but renamed NSI in 1975.) The

32. Charles Sheldon, “National Goals in Space,” in ibid., pp. 71–93, quote from p. 74. Sheldon’s rationale for spaceflight also cited its contributions to national security, technological spinoffs, economic benefits, the advancement of science, and national prestige—values that continue to be cited by advocates of spaceflight and in U.S. space policy.
33. Burrows, This New Ocean, p. 332. It should be noted that the frontier metaphor is noticeably absent from other national cultural narratives of spaceflight. Although the word “frontier” does appear from time to time in European space policy discourse, in those contexts it does not appear to mean the same thing as it does in American contexts. See, for example, the European Space Agency (ESA)’s use of the tag line “expanding frontiers” in public documents (http://www.esa.int) and the European Commission’s reference to space as “a new European frontier.” See European Commission, Space: a New European Frontier for an Expanding Union: An Action Plan for Implementing the European Space Policy (Luxembourg: European Communities, 2000).
NSI changed its name to the National Space Society shortly before its 1987 merger with the L5 Society.34

The NSS says its rationale for promoting space settlement is “survival of the human species.” Among the values and beliefs articulated in the Society’s “vision” for space exploration and development are “prosperity—unlimited resources,” “growth—unlimited room for expansion,” individual rights, unrestricted access to space, personal property rights, free-market economics, democratic values—and also enhancement of Earth’s ecology and protection of new environments.35

Gerard K. O’Neill formed his own advocacy group, the Space Studies Institute (SSI), in 1977 to promote his colonization agenda. The SSI’s stated mission is “opening the energy and material resources of space for human benefit . . . to make possible the productive use of the abundant resources in space.”36 Meanwhile, Freeman Dyson updated his spaceflight rationale for the 1970s, writing: “There are three reasons why, quite apart from scientific considerations,” human spaceflight is necessary: first, “garbage disposal; we need to transfer industrial processes into space so that the earth may remain a green and pleasant place”; second, “to escape material impoverishment”; and third, “our spiritual need for an open frontier. The ultimate purpose is to bring humanity . . . a real expansion of our spirit.”37

In the 1980s, the era of NASA’s Space Shuttle and space station programs, the space community, as Burrows has noted, heavily promoted human spaceflight: “At the heart of it all, as usual, [were] the core of dreamers . . . who steadfastly believed it was their race’s manifest destiny to leave Earth for both adventure and survival.”38 In 1988, some of those believers created the Space Frontier Foundation (SFF) to promote “opening the space frontier to human settlement as rapidly as possible.” This group says its “purpose is to unleash the power of free enterprise and lead a united humanity permanently into the Solar System.” Like the NSS, the SFF espouses

34. Richard Godwin, “The History of the National Space Society,” Ad Astra (16 November 2005), http://www.space.com/adastra/adastra_nss_history_051116.html (accessed July 14, 2006). Interestingly, the combined membership of NSS and L5 voted after the merger of their groups to continue to use the NSS name instead of renaming their combined group the Space Frontier Society. Aerospace industry groups such as the Aerospace Industries Association, the American Institute of Aeronautics and Astronautics, the American Astronautical Society, and the Space Foundation play an important role in U.S. spaceflight advocacy, but they do so more by pragmatic actions, such as influencing legislation and policy-making, than by sustaining an ideology of spaceflight in public discourse.

35. See the National Space Society Web site for information on this subject, http://www.nss.org (accessed 10 June 2006). Interestingly, some of these beliefs appear to be in conflict with others.

38. Burrows, This New Ocean, p. 507.
a conflicting set of goals, including “protecting the Earth’s fragile biosphere and creating a freer and more prosperous life for each generation by using the unlimited energy and material resources of space.” Its stated strategy for achieving these goals is “to wage a war of ideas in the popular culture” and transform U.S. spaceflight “from a government program for the few to an open frontier for everyone.”

In a series of essays called “The Frontier Files,” SFF founder and director Rick Tumlinson offers his version of the space frontier narrative:

We . . . see our civilization at a crossroads . . . . Down one path is a future of limits to growth, environmental degradation and ultimately extinction. Down the other path lie limitless growth, an environmentally pristine Earth and an open and free frontier in space.

Regarding the purpose of spaceflight, he asserts:

The one necessary and sufficient reason we are called to the Space Frontier is buried deep within us. It is a feeling . . . [a] calling to go, to see, to do, to be “there.” We believe Homo Sapiens is a frontier creature. It is what we do, it defines what we are.

In 1987, writer Marshall Savage founded the First Millennial Foundation and joined the chorus of advocates claiming humans are destined to colonize the universe:

Now is the watershed of Cosmic history. We stand at the threshold of the New Millennium. Behind us yawn the chasms of the primordial past . . . before us rise the broad sunlit uplands of a living cosmos . . . . The future of the universe hinges on what we do next. If we . . . stride into space as the torchbearers of Life, this universe will be aborning.

Earth is slipping “into a pit of our own digging,” according to Savage, and in order to save itself, humankind must expand into the cosmos: “[I]t is our policy to enliven this sterile universe . . . . If we . . . forsake our cosmic destiny, we will commit a crime of unutterable magnitude.”

The Mars Society, founded in 1998, advocates pioneering the space frontier by the human settlement of Mars. Mars Society founder Robert Zubrin has said he embraces “Turner’s belief that the frontier is a crucial part of the American character . . . I would like to see our traditions carried forward.”43 According to the Mars Society’s “founding declaration,”

Civilizations, like people, thrive on challenge and decay without it . . . . As the world moves towards unity, we must join together . . . facing outward to embrace a greater and nobler challenge . . . . Pioneering Mars will provide such a challenge . . . . A humans-to-Mars program would challenge young people everywhere to develop their minds to participate in the pioneering of a new world . . . . The settling of the Martian New World is an opportunity for a noble experiment in which humanity has another chance to shed old baggage and begin the world anew; carrying forward as much of the best of our heritage as possible and leaving the worst behind . . . . [E]xploration and settlement of Mars is one of the greatest human endeavors possible in our time . . . . No nobler cause has ever been.44

**Government Space Rhetoric**

The frontier metaphor, the ideology of progress and the belief in American exceptionalism have been prevalent in government space policy rhetoric as well as the rhetoric of advocacy groups. The National Commission on Space, appointed by President Reagan to develop long-term goals for U.S. civilian space exploration, entitled its final report “Pioneering the Space Frontier” and described in it “a pioneering mission for 21st-century America: to lead the exploration and development of the space frontier.” Humankind is “destined to expand to other worlds,” the commission said in its report, and “our purpose” is to establish “free societies on new worlds.” Toward achieving those goals, “we must stimulate individual initiative and free enterprise in space.”45

The rhetoric of American exceptionalism remained apparent in space policy documents of the George H. W. Bush administration: “America’s space program is what civilization needs . . . . America, with its tremendous resources, is uniquely qualified for leadership in space . . . . our success will be guaranteed by the American spirit—that same spirit that tamed the North American continent and built enduring

democracy.” The “prime objective” of the U.S. space program is “to open the space frontier.”  

NASA declared in its 90-day study of this Space Exploration Initiative, “The imperative to explore” is embedded in our history . . . traditions, and national character,” and space is “the frontier” to be explored. 

“Space is the new frontier,” said another space study group of that time, where the United States will find “a future of peace, strength, and prosperity.” 

In keeping with rhetorical tradition, the Clinton administration declared, “Space exploration has become an integral part of our national character, capturing the spirit of optimism and adventure that has defined this country from its beginnings . . . Its lineage is part of an ancient heritage of the human race . . . deep in the human psyche and perhaps in our genes.” 

In the George W. Bush administration, White House Office of Science and Technology Policy Director John Marburger has said the point of the president’s so-called vision for space exploration “is to begin preparing now for a future in which the material trapped in the Sun’s vicinity is available for incorporation into our way of life.” 

NASA Administrator Michael Griffin has said that the aim of space exploration is “to make the expansion and development of the space frontier an integral part of what it is that human societies do.” Griffin has said that when human civilization reaches the point where more people are living off Earth than on it, “we want their culture to be Western.” He has asserted that Western civilization is “the best we’ve seen so far in human history,” and that the values space-faring people should take with them into space should be Western values. “We want to be the world’s preeminent space-faring nation for all future time,” he said on another occasion, “second to none.” Griffin has said that space exploration has something to do with “core beliefs” about what societies and civilizations should be doing “on the frontiers of their time . . . North Americans are the way we are because of the challenges of the frontier . . . I believe that Western thought, civilization, and ideals represent a superior set of values,” better
than those of civilizations that came before. These values are “irretrievably linked to” expansion, he has said, and now this expansion will continue into the human frontier of space.\textsuperscript{54} Most recently, Griffin has said:

\begin{quote}
It is in the nature of humans to find, to define, to explore and to push back the frontier. And in our time, the frontier is space and will be for a very long time . . . . The nations that are preeminent in their time are those nations that dominate the frontiers of their time. The failed societies are the ones that pull back from the frontier. I want our society, America, [W]estern society, to be preeminent in the world of the future and I want us not to be a failed society. And the way to do that, universally so, is to push the frontier.\textsuperscript{55}
\end{quote}

**Conclusions**

This brief historical review has shown how the rhetoric of space advocacy has sustained an ideology of American exceptionalism and reinforced long-standing beliefs in progress, growth, and capitalist democracy. This rhetoric conveys an ideology of spaceflight that could be described, at its worst, as a sort of space fundamentalism: an exclusive belief system that rejects as unenlightened those who do not advocate the colonization, exploitation, and development of space.\textsuperscript{56} The rhetorical strategy of space advocates has tended to rest on the assumption that the values of “believers” are (or should be) shared by others as well.

Although the social, political, economic, and cultural context for space exploration has changed radically since the 1960s, the rhetoric of space advocacy has not. In the twenty-first century, advocates continue to promote spaceflight as a biological imperative and a means of extending U.S. free enterprise, with its private property claims, resource exploitation, and commercial development, into the solar system and beyond. Pyne, among others, has addressed the problematic nature of these arguments: “The theses advanced to promote [solar system] settlement,” he noted,

\textsuperscript{54} Griffin made these remarks at a meeting of the NASA Advisory Council’s science subcommittees in Washington, DC, on 6 July 2006. The author attended this event.

“are historical, culturally bound, and selectively anecdotal: that we need to pioneer to be what we are, that new colonies are a means of renewing civilization.”

Spaceflight advocacy can be examined as a cultural ritual, performed by means of communication (rhetoric), for the purpose of maintaining the current social order, with its lopsided distribution of power and resources, and perpetuating the values of those in control of that order (materialism, consumerism, technological progress, private property rights, capitalist democracy). Communication research has shown how public discourses—those cultural narratives or national myths—“often function covertly to legitimate the power of elite social classes.” And this review has shown how the rhetoric of space advocacy reflects an assumption that these values are worth extending into the solar system.

“Everything now suggests,” Nisbet wrote 25 years ago, “that Western faith in the dogma of progress is waning rapidly.” This faith appears to have remained alive and well, however, in the ideology of spaceflight. Christopher Lasch wrote 15 years ago, “Almost everyone now agrees that [the idea of] progress—in its utopian form at least,” no longer has the power “to explain events or inspire [people] to constructive action.” But in the current cultural environment, perhaps it does—at least among space advocates. Progress is, indeed, modern American dogma and a key element of pro-space dogma. But it does not resonate well—as Pyne and others have noted—in the current postmodern (or even post-postmodern) cultural environment, where public discourse is rife with critiques of science, technology, the aims of the military-industrial complex, and the corporate drive for profit.

Pyne observed almost 20 years ago that space exploration was “not yet fully in sync” with its cultural environment. Modern (seventeenth- to twentieth-century) Western (European-American) exploration functioned as “a means of knowing, of creating commercial empires, of outmaneuvering political economic, religious, and military competitors—it was war, diplomacy, proselytizing, scholarship, and trade by other means.” But the postmodern exploration of space is different. Outer space is not simply an extension of Earth and the era of space exploration is not simply an extension of the modern era of transoceanic and transcontinental exploration. Its cultural context is different. The modern phenomenon of spaceflight has outlived the

modern era and its purpose is not clear in a postmodern or even post-postmodern world, characterized by uncertainty, subjectivity, deconstruction, and a rejection of so-called master narratives such as the story of frontier conquest. The moral imperative of the myth of pioneering the space frontier could be interpreted as a narrative that is in tune with its postmodern cultural environment in the sense that it conveys the values of the dominant social order—that is, what communication scholar Herb Schiller has called “the transnational corporate business order” and its ideology of private property ownership, resource exploitation and profit building.63

Of course, the idea of the human colonization of space is not publicly compelling in the current cultural environment. Poet Wendell Berry has addressed this dilemma:

The [space colonization] project is an ideal solution to the moral dilemma of all those in this society who cannot face the necessities of meaningful change. It is superbly attuned to the wishes of the corporation executives, bureaucrats, militarists, political operators, and scientific experts who are the chief beneficiaries of the forces that have produced our crisis . . . .

If it should be implemented, it will be the rebirth of the idea of Progress with all its old lust for unrestrained expansion, its totalitarian concentrations of energy and wealth, its obliviousness to the concerns of character and community, its exclusive reliance on technical and economic criteria, its disinterest in consequence, its contempt for human value, its compulsive salesmanship.

The sales pitch for space colonization goes this way, according to Berry:

If we will just have the good sense to spend one hundred billion dollars on a space colony, we will thereby produce more money and more jobs, raise the standard of living, help the underdeveloped, increase freedom and opportunity, fulfill the deeper needs of the human spirit etc. etc. . . . Anyone who has listened to the arguments of the Army Corps of Engineers, the strip miners, the Defense Department or any club of boosters will find all this dishearteningly familiar.64

63. Herbert Schiller, “Not Yet the Post-Imperialist Era,” in Media and Cultural Studies: Key Works, rev. edition, M. G. Durham and D. M. Kellner, eds. (Malden, MA: Blackwell, 2006), pp. 295–310, quote from p. 303. Retired congressional Research Service analyst Eilene Galloway, arguably the oldest living expert on space law and policy at age 100 in 2006, has often said that problems in space policy are due at least in part to the fact that there are too many people in the space community who think that outer space is just like Earth.

Visions of the human colonization of space present a “moral law of the frontier” that is disturbing, Berry concludes: this law is that “humans are destructive in proportion to their supposition of abundance; if they are faced with an infinite abundance, then they will become infinitely destructive.”

Berry wrote his essay about the downside of space colonization in the 1970s. But his views are not necessarily out of date. Environmentalists might argue today that the case Berry made against space colonization is even more relevant today than it was in the 1970s.

In order to survive as a cultural institution, spaceflight needs an ideology. It needs to have some connection to widely held beliefs. It needs a role in a cultural narrative. But as Pyne has noted, “Locating exploration in the human gene or in the human spirit” and not in specific cultures is not viable. Continued reliance on this narrative “only absolves us from making those vital, deliberate choices” we inevitably have to make—about how we should proceed into space, and what values space exploration should embody. “These choices,” Pyne has said, “are not intuitive.” As a cultural institution, space exploration “has to speak to deeper longings and fears and folk identities.” It “is not merely an expression of curiosity but involves the encounter with a world beyond our ken that challenges our sense of who we are. It is a moral act . . . more than adventuring, more than entertainment, more than inquisitiveness.” It has to explain “who a people are and how they should behave.”

And in the current cultural environment, as Pyne has observed, space exploration “will have to base its claim to legitimacy on transnational or ecumenical values.”

Unlike the Western American frontier, as Janice Hocker Rushing has pointed out, space is too big to be conquered. The recent focus of space exploration on the search for evidence of extraterrestrial life is a product, she has said, of a widespread understanding that humankind exists in a universe, not only on planet Earth. The narrative of space exploration today might better reflect this understanding by telling a story of “a spiritual humbling of self” rather than “an imperialistic grabbing of territory.”

Although she has noted that “the WASP space cowboy version of spaceflight” has persisted from the Apollo era into the present, Constance Penley also has observed that NASA “is still the most popular point of reference for utopian ideas of collective progress.” In the popular imagination, “NASA continues to represent . . . perseverance, cooperation, creativity and vision,” and these meanings embedded in the narrative of spaceflight “can still be mobilized to rejuvenate the near-moribund idea of a future toward which dedicated people . . . could work together for the common good.”

65. Ibid.
This historical review of the rhetoric of space advocacy reveals competing American cultural narratives, then. The dominant narrative—advancing the values of the dominant culture—upon which the narrative of U.S. spaceflight piggybacks, is a story of American exceptionalism that justifies unilateral action and the globalization of American capitalist democracy and material progress. The story of spaceflight is embedded in this broader narrative. That story is also woven into a competing narrative, a vision of “utopian ideas of collective progress” and “a spiritual humbling of self.” This competing narrative may be a site within which the ideology of spaceflight might rejuvenate itself—where the vision of a human future in space becomes a vision of humanity’s collective peaceful existence on Spaceship Earth and the need to work together to preserve life here and look for life out there.
Spaceflight in popular culture has served two important functions—apart from its entertainment value, that is. First, it served to inspire at a time when the entire notion of traveling into space or to other worlds was an idea beneath the contempt of most scientists and engineers. It not only inspired, it carried the torch for the centuries it took for technology to finally make space travel a reality. Second, it acted—and still acts—as a mirror or gauge of both public interest in spaceflight and the state of contemporary astronautical science. For instance, Jules Verne shot his fictional projectile into space by means of a giant cannon\(^1\) simply because his readers would have never believed that contemporary rockets would have been capable of such a feat, while only 50 years later Arthur Train and Robert Wood were able to describe a spaceship propelled by a beam of alpha particles produced by the disintegration of uranium in their remarkable novel, *The Moon-Maker* (1917).\(^2\)

The Dreamers

Astronautics is unique among all the sciences in that it owes its origins to an art form. Long before engineers and scientists took the possibility of spaceflight seriously, virtually all of its aspects were first explored in art and literature, and long before the scientists themselves were taken seriously, the arts kept the torch of interest burning.

Although there had been numerous early fantasies about trips to the Moon, no one really considered the genuine possibility of spaceflight until two important events occurred: first, the discovery that there were places in the universe other than Earth, and second, that there might exist the technology for getting there. These events took place about 250 years apart. The first occurred in 1610 when Galileo first turned his telescope toward the heavens and discovered that the planets were not just a special class of wandering stars but real worlds in their own right.

---

showed phases just like the Moon; Mars had dusky markings; and Jupiter possessed four tiny moons of its own, like a miniature solar system.

At about the same time that Galileo and the astronomers who followed him were discovering new worlds in our solar system, so were other explorers finding new worlds on the other side of the Atlantic Ocean. That the Moon was now included in geographies such as Peter Heylyn’s *Cosmographie* of 1682 is indicative of its new status as an equal among other new worlds such as North and South America.3

By the time Galileo had observed the craters of the Moon and Jupiter’s satellites, hundreds of ships and thousands of explorers, colonists, soldiers, and adventurers had made the journey to the amazingly rich and fertile lands of the New World. Now that human beings had learned that were there not only new worlds here upon Earth, but unknown lands in the sky as well, it’s not very surprising that the discoveries being made by astronomers were quickly followed by a yearning expressed by an unprecedented spate of space travel stories. If these new lands could not be reached in reality, then they would be explored by proxy. Although most of these authors had little or no interest in the realistic depiction of science, their books were nevertheless an accurate barometer of the ever-increasing interest in the possibility of exploring the planets.

Many authors wrote of trips to the Moon in the decades following Galileo’s discovery. In 1622, Charles Sorel wrote of “great Engins” that might carry people to the Moon, or that they might get there by means of “all manner of structures, and ladders.”4 In 1638, Francis Godwin published *The Man in the Moone*, in which his hero is carried to that world by a flock of geese who regularly migrate between Earth and the Moon.5 The great scientist Johannes Kepler—who established the laws of orbiting bodies—wrote a novel called *Somnium* in 1634.6 Its hero is carried to our satellite by demons along the bridge of darkness that occurs during an eclipse of the Moon. Although his method of getting to the Moon was highly unscientific, Kepler’s descriptions of the conditions there were very accurate in light of what was known about the Moon at that time (for instance, Kepler was aware of the fact that most of the journey would have to be made in a vacuum and that the surface of the Moon would be desolate, alternating between extremes of heat and cold).

Cyrano de Bergerac made fun of such fanciful voyages in his *Comic History* (1657), in which he tried to come up with as many utterly ridiculous methods of space travel as he could think of. Ironically, one he thought was funniest was the use of rockets! Although he was probably the first person in history to suggest the use of rockets for launching a spacecraft, he only gets half a point for thinking it was a silly idea.7

---

5. Ibid., p.11.
6. Ibid., p.10.
The second great event in the history of the popular conception of space travel occurred in 1783 when two Frenchmen, brothers Étienne and Joseph Montgolfier, invented the balloon. For the first time, human beings were able to ascend above Earth farther than they could jump. These two events launched avalanches of speculative literature about the possibility of traveling beyond Earth and what might be found on these new worlds. Here at last seemed to be an answer to all those who had been looking at the starry sky with longing. If human inventiveness could devise a way of rising a few thousand feet above the surface of Earth, what was a mere quarter-million miles to the Moon but a matter of degree? Science and technology had conquered the sky—it had to be only a matter of time before they conquered space as well.

Needless to say, writers quickly abandoned their swans and dream-demons and turned to balloons to carry their heroes to the Moon and all over the solar system. But if science was marching ahead, so were the ever-more-knowledgeable readers of these books. The widespread fascination with science that occurred at the end of the eighteenth century also meant that most readers were becoming too knowledgeable about the subject to accept even balloons as a realistic method of getting to the Moon, let alone anything less scientific or technological. Authors were forced to come up with more realistic, believable methods of space travel.

One of the first to do so was the American author George Tucker. Although the spaceship in his 1827 novel, *A Voyage to the Moon*, employed an imaginary antigravitational material, Tucker gave great thought to the actual conditions that might exist beyond Earth’s atmosphere and how his vehicle would have to deal with them. What he ended up with might be the very first description of a spaceship that took into account the conditions of outer space as they were known at the time. For instance, the spacecraft—a 6-foot (2-meter), copper-clad cube—is carefully tested to make sure that it is perfectly airtight, while compressed air for breathing is carried in tanks. The walls are even insulated to protect the astronauts from the cold of space.

Tucker was one of Edgar Allan Poe’s instructors at the University of Virginia and his novel may have inspired Poe to write his own Moon travel story, “The Unparalleled Adventures of One Hans Pfaal” (1835). Although Poe used a balloon, he still paid more careful attention to science and technology than had any other author before him. For instance, the sealed, spherical gondola of his hero’s balloon closely resembles those used by stratosphere balloonists and his descriptions of high-altitude flight and Earth as seen from space might have been written by a present-day astronaut.

Poe rationalized the use of a balloon by assuming that Earth’s atmosphere extends as far as the Moon, albeit very tenuously:

---

I . . . considered that, provided in my passage I found the medium I had imagined, and provided that it should prove to be essentially what we denominate atmospheric air, it could make comparatively little difference at what extreme state of rarefaction I should discover it—that is to say, in regard to my power of ascending—for the gas in the balloon would not only be itself subject to similar rarefaction . . . but, being what it was, would, at all events, continue specifically lighter than any compound of whatever mere nitrogen and oxygen. Thus, there was a chance—in fact, there was a strong probability—that, at no epoch of my ascent, I should reach a point where the united weights of my immense balloon, the inconceivably rare gas within it, the car, its contents, should equal the weight of the mass of the surrounding atmosphere displaced.¹⁰

To rise into this infinitely thin atmosphere, Poe’s balloon is filled with a new gas “37.4 times lighter than hydrogen”—and he also had his hero take advantage of the diminishing gravitational pull of Earth as the balloon traveled farther and farther from it.¹¹

Almost all of this was sheer pseudoscientific mumbo-jumbo, of course, but Poe’s readers did not know this. No one had ever spoken about a trip to the Moon in such detailed, scientific-sounding terms before. What is important is that for the first time it had become necessary to provide an interplanetary story with the trappings of real science. This is what makes Poe’s story so significant. He realized that it was no longer sufficient to simply enable a character to reach the planets by fiat. By the time Poe was writing, the conditions at high altitudes were becoming well known and astronomers were becoming more assured about the nature of outer space and the prevailing conditions on our own satellite. An author writing a story set in these places could no longer blithely ignore this knowledge.

Poe himself was perfectly aware of the uniqueness of what he had done. In his postscript to “Hans Pfaal,” he reminded his readers that the intent of earlier Moon journeys had been satirical; the theme being a description of Lunarian customs as compared with ours. In none, is there any effort at plausibility in the details of the voyage itself. The writers seem, in each instance, to be utterly uninformed in respect to astronomy. In Hans Pfaal the design is original, inasmuch as regards an attempt at verisimilitude, in the application of scientific principles (so far as the whimsical nature of the subject would permit), to the actual passage between the earth and the moon.¹²

¹¹. Ibid., p. 108.
¹². Ibid., p. 112.
By the time Poe was writing, the world had been undergoing an industrial, technological, and scientific revolution. By the time the Montgolfiers had flown their first balloon, the steam engine had already been invented, as had the spinning jenny, the circular saw, and electric generators. Only two years earlier Uranus, a brand-new planet, had been discovered, revealing that the classical solar system known since ancient times was not the limit to the new frontier in the sky. In the half-century following the balloon came the iron plow, the power loom, the first crossing of the Atlantic by a steamship, the first railways, the electric storage battery and motor, the telegraph, cameras, and the revolver. People living in the nineteenth century had good reason for thinking that science could do anything. There seemed to be nothing that scientists or engineers could not understand or conquer. The worlds of the solar system differed only in a matter of scale from Africa or the Poles. Surely, if humans were going to leave Earth and travel to these other planets, then it would be science and technology that would provide the means. By the middle of the century, generals, admirals, and explorers had been replaced by a new hero: the engineer.

Still, no one seriously considered the actual technological problems of spaceflight until 1865, when French author Jules Verne wrote his classic novel *From the Earth to the Moon* (its sequel, *Round the Moon*, was published in 1870). Before then, all space travel stories had been fantasies to a greater or lesser degree. But Verne had been a great fan of Edgar Allan Poe and took his lead from Poe’s invention of scientific verisimilitude—developing it to a degree Poe never imagined.

In Verne’s story, a group of American arms manufacturers find themselves with nothing to do after the close of the Civil War. As an outlet for their energies and creative genius, they propose building an enormous cannon—actually a 900-foot (275-meter) deep, cast iron–lined well with 400,000 lbs (8,000 kg) of explosives at the bottom—and launching a projectile to

Figure 26.1—This illustration of the launch of Jules Verne’s projectile accompanied the original edition of *From the Earth to the Moon*. Although Verne’s giant cannon was impossible (at least so far as launching passenger-carrying spacecraft is concerned), he was well aware of this and took great care in making the device at least appear plausible. The result was a novel that inspired generations to take the idea of spaceflight seriously, including many of the seminal founders of astronautics. (*Author’s collection.*)

13. Verne, *From the Earth to the Moon*. 
the Moon. It eventually dawns on them that it would be much more interesting to not just launch an ordinary projectile but one carrying passengers. Of course, this would never really work—the shock of going from a standing start to 7 miles (11 km) a second in 900 feet (275 meters) would have been instantly fatal to his heroes—but there is compelling internal evidence that Verne realized this and consequently filled his book with so much science and math and engineering that his nineteenth-century readers accepted his story without question. So much so, in fact, that when the novel was originally serialized in France, people wrote to the author volunteering to be passengers in the projectile!

Each chapter of the book is devoted to a different problem facing the space explorers: the method for leaving Earth, the design and construction of the giant cannon, what its explosive charge would consist of, where the cannon would be located, what the projectile would be made of, what its speed and trajectory would need to be, the best time and date for the launch, safety precautions, experimental tests, provisions for life support, methods for tracking the projectile, and how all of this was going to be paid for. All of these questions and more Verne answers in precise detail, even to the point of quoting the actual math used in his calculations (actually performed by his cousin, Henri Garcet of the Lycée Henri-IV).4

With the publication of Verne’s novel, the possibility of spaceflight was instantly transformed from the realm of the fantastic to a mere exercise in Victorian engineering. For the first time, the problem of space travel had been put on a firm mathematical and technological basis. Indeed, there is some reason to argue for Verne having literally invented the science of astronautics. Verne’s method for getting his astronauts into space would not work in reality, but what was important was that he suggested a method that employed nothing but known materials and contemporary technologies. His astronauts did not need to rely upon impossible balloons or imaginary antigravity metals. He demonstrated to his readers one monumentally important fact: the conquest of space was to be a matter of applied mathematics and engineering and nothing else.

Although Verne used a giant cannon instead of rockets to launch his heroes into space, he was perfectly aware of the potential rockets had. But he was also aware that the state of the art of rocketry in the mid-1800s was such that his readers would have never believed that the unreliable, inefficient, and not very powerful rockets then available would ever be capable of speeding a spaceship to the Moon. Still, Verne did have his astronauts carry rockets on board for their eventual (albeit aborted) landing on the Moon and for steering the projectile. In this, Verne was one of the very first to realize that rockets would work in a vacuum and would be the ideal source of propulsion in space—a fact that eluded all but a very few writers and scientists until the early years of the twentieth century.

Verne’s novel was a great success and was translated and published all over the world. It had readers and admirers in almost every nation, and some of these readers were not just admirers—they were inspired to actually do what Verne had only written about. Konstantin Tsiolkovskiy, Hermann Oberth, Robert Goddard, and many other early pioneers of rocketry and astronautics were directly inspired by the space novels of Jules Verne and others.

By the time the first spacecraft was launched in 1957, most of the problems facing engineers had been solved—or at least dealt with—by the writers of space fiction. This is not because science-fiction writers were more prescient; it’s simply because they were forced to solve many of the same problems long before engineers had to, and there are only so many different plausible answers.

**The Rocketeers**

The period between World War I and World War II was a mixed bag as far as popular interest in space travel was concerned. Aviation was the great technological craze of the time (rivaled only by radio) and rockets seemed something of a trivial side-issue. Robert Goddard had, of course, launched the world’s first liquid-fuel rocket in 1926, but the news of this was barely known within scientific circles, let alone the general public. Goddard was much better known as the man who was going to send a rocket to the Moon. In April 1920 he had written an article for *Popular Science* magazine in which he described the possibility of hitting the Moon with a rocket carrying 14 lbs (6 kg) of flash powder—enough, he had calculated, to create a flash visible from Earth. This article immediately made Goddard something he had never had any wish to be: a media celebrity. Scientists and popular-science writers in publications ranging from the *London Graphic* and *Scientific American* to *The New York Times* took Goddard to task for what they considered his utter lack of rudimentary scientific knowledge, while at the same time popular magazines took Goddard dead seriously and published scores of articles on the possibility of spaceflight, often comparing it, rightly, to the advances then occurring in aviation. Many of these were translated reprints of articles originally written by Austrian Max Valier, one of the most enthusiastic and colorful of the rocketry and space travel enthusiasts who were just then beginning to organize in Europe. Valier’s ubiquitous writing and spaceship designs (beautifully illustrated by the Römer brothers) influenced science and science-fiction writers, and even appeared in some of the first space movies ever produced, in much the same way that Wernher von Braun’s widely distributed designs influenced the public perception of spacecraft in the 1950s and 1960s.\(^\text{15}\)

\(^{15}\) Ibid., pp. 123–124.

\(^{16}\) Ibid., pp. 144–146.
On the whole, however, the era of the 1920s and 1930s was not a bright one for the depiction of space travel in the media or for its impression on the public at large. Most work on liquid-fuel rockets was being done either in secrecy (by a humiliated and bitter Goddard, who now wanted more than anything else to avoid publicity) or by small groups of amateurs in Europe. “Rocket” to the general public still meant the gunpowder variety familiar to Fourth of July celebrants and Civil War veterans. Although Valier and others had shown that rockets could efficiently propel every sort of vehicle, from cars to sleds to aircraft, these were for the most part seen for the publicity stunts they were and, since almost all of these employed powder rockets, they really did not go very far in educating the public on the possibilities of the liquid-fuel rocket.

The ideas published by Goddard—and the reporting and misreporting of them in the media—combined with the popular writings of Valier and the publicity generated by his experiments, impacted popular culture in only one major way, and it was in a form that was actually a setback for the acceptance of astronautics. This was the introduction of, first, Buck Rogers and then Flash Gordon, two wildly popular comic strip characters whose improbable adventures in space quickly made the transition from the newspaper comic pages to motion picture serials that are still shown today. Inspired by the success of his 1929 novel, Armageddon 2419 AD, author Philip Nowlan adapted his hero for a newspaper comic strip, drawn by Dick Calkins. Although Buck Rogers’s name has become synonymous with space travel, spaceships did not make an appearance until 1930, after nearly 400 daily strips had been published (although rocket-powered aircraft were introduced in strip 90 in 1929).17

Although the early space travel strips had a relatively high standard of scientific accuracy, this was not maintained. By the 1940s, Buck Rogers had descended into utter fantasy. The believable spacecraft of the early 1930s had degenerated into art nouveau monstrosities that would have done credit to Dr. Seuss. This left a lasting impression on a prewar generation who came to derogatorily refer to space travel as “that Buck Rogers thing.”

The Golden Age of Spaceflight

It may seem odd to say so, but the Golden Age of space travel occurred before space travel became a reality. It was a period between the end of World War II and 1961 that is analogous to, say, the 1920s and 1930s in aviation—a time when the public had gone aviation-mad.

Much the same thing occurred in the two decades following World War II. Fueled in large part by postwar optimism combined with a faith in technology and engineering like that of the nineteenth century, the possibility of spaceflight

17. Ibid., pp. 182–183.
took a firm hold on the public imagination. There were references to rockets and space travel everywhere one looked, from television and movies to the pages of the Sunday comics to the hood ornaments of the latest-model Oldsmobile Rocket 88. There were rocket toys and space games, bubblegum cards and gumball machines, cigarette lighters and bedside lamps, breakfast cereal premiums and Buck Rogers Popsicles, and comic books and television serials. A recent collectibles catalog lists more than 300 toys inspired by the most popular children’s television space shows of the 1950s: Space Patrol, Captain Video, Tom Corbett, and Rocky Jones.

Hardly a week went by without an article in at least one national magazine about the coming age of spaceflight. All of this—bad science and good—helped counteract some of the negative effects the depiction of spaceflight in popular culture had created. The popularity of Buck Rogers and Flash Gordon in the 1930s and 1940s—abetted by the series of movie serials they inspired—did little to help the cause. Their emphasis on swashbuckling romance and utter disregard for anything resembling science led too many people—layman and scientist alike—to dismiss the entire concept of space travel as “that crazy Buck Rogers idea.”

There has been nothing since the Golden Age that remotely parallels its frenzy about spaceflight, perhaps for the same reason the Golden Age of aviation finally ended: spaceflight became a reality. Just as transatlantic flights stopped making headlines when anyone could get a seat on a regularly scheduled airliner, much of the hold space travel had on the popular imagination faded as flights into space became commonplace.

Why this sudden postwar enthusiasm for space travel, especially since a decade earlier it had been considered a subject fit only for comic strips? A lot of it had to do with advancements in science and technology generally that occurred during the war. Jets and rocket-powered aircraft had shown their mettle as being more than hare-brained publicity stunts. American bomber crews and fighter pilots had brought back stories of incredible German aircraft such as the Messerschmitt Me-109 Komet and Me-262 rocket and jet fighters. Then, of course, there were the giant V-2 rockets that had fallen on England. It was obvious to more than just scientists and space travel enthusiasts that if the V-2 was not a real spaceship, it was mighty close to the real thing.

Given the history of astronautics’ close relationship with the arts, perhaps it is only natural that the prime instigators of the Golden Age were a rocket scientist and an artist. The team of Wernher von Braun and Chesley Bonestell were as responsible for the almost universal public enthusiasm for spaceflight as anyone. Bonestell’s first book, The Conquest of Space (1949), had galvanized its readers. The reaction was much the same as to Galileo’s revelations more than 300 years earlier. Although

---

most people were aware of the planets in a kind of abstract sense, few had thought
of them as real worlds like Earth, with landscapes and scenery as fascinating as
anything that existed on our own planet. Bonestell’s depictions of Mars and the
moons of Jupiter and Saturn did not bear the stigma of “artist’s impression”—
they looked instead like postcards from the future. There was no sensationalism or
exaggeration, just a cold-blooded, matter-of-fact representation of places that really
existed, presented with no more fanfare than your neighbor’s snapshots from their
summer vacation in Yosemite.20

It was pretty much a given that Bonestell would be invited to illustrate a series
of magazine articles being created by von Braun about the near future of spaceflight.
The series, written by von Braun and a number of other space experts, repeated Jules
Verne’s accomplishment by demonstrating that spaceflight could be achieved using only
contemporary technology and materials available at the time. It is true that von Braun’s
giant ferry rockets (the first stage of which would have had 51 separate rocket engines!),
lunar landers, and space station might not have been the most practical possible designs,
but that was not his point. Anything else would have required speculating on future
developments; he wanted to show that spaceflight was possible in 1952, not 2002.21

It is difficult to gauge the full effect the subsequent Collier’s magazine series had
on both the public imagination and the contemporary development of America’s
fledgling space program. Perhaps one way to judge this is by looking at the
artifacts of the time. Collier’s spaceships were literally everywhere. When Bonestell’s
paintings were not being legally reprinted, they were plagiarized. And where they
were not being copied outright, they were being inspirational. One
can find Collier’s-inspired spacecraft

Figure 26.2—This painting by Chesley Bonestell was
created for the Wernher von Braun book, The Exploration
of Mars (1954). von Braun had developed a detailed,
consistent, incremental plan for the exploration of
space. In much the same way that Jules Verne had, a
century earlier, shown that spaceflight was merely a
matter of applied mathematics and engineering, von
Braun’s magazine series and books helped to not only
convince a skeptical public that spaceflight was possible
using contemporary techniques and materials, but to
also make the idea of spaceflight wildly popular. (Artwork

21. Frederick I. Ordway and Randy Liebermann, eds., Blueprint for Space (Washington, DC:
throughout those decades, from plastic model kits to coloring books, from science-fiction movies to sterling silver money clips! A number of years ago I started a file of Bonestell-inspired artwork and had to quit when it grew to more than two inches in thickness.

In the movie theaters, space travel films had not yet begun to descend into the abyss of alien-ridden space opera. Films such as Destination Moon (1950), Conquest of Space (1955), and even Forbidden Planet (1956) were filled with good science and positive images about the future of spaceflight. On television, series such as Tom Corbett employed the advice of experts such as Willy Ley to lend their programs authenticity, while the arrival of a full-size Space Patrol “rocket ship” in a town or city was a full-scale media event. Meanwhile, more nonfiction books about rocketry and space travel were being published for young readers than at any time before or since.

One of the most important of the legitimate spinoffs of the Collier's articles was a series of programs broadcast as part of Walt Disney's Disneyland television show, which had begun airing in 1954. Inspired by the popularity of the recently published magazine series as well as by the increasing public interest in space travel, Disney produced three short films about the future of space exploration: Man In Space, Man and the Moon and Mars and Beyond. Employing state-of-the-art animation and special effects, combined with the expertise of von Braun, Heinz Haber, Ernst Stuhlinger, and Willy Ley, the shows outlined the history of rocketry and a von Braun-inspired, step-by-step program for the exploration of space—upgraded from the scheme he had earlier proposed in Collier's. The series also introduced the American public to the concept of the electric space ship, as proposed by Stuhlinger. The first show was broadcast on 9 March 1955 to an audience of nearly 100 million people—more than half the total population of the United States.23

One of these viewers was President Dwight Eisenhower, who borrowed a copy for two weeks to show to officials at the Pentagon. On 29 July, Eisenhower announced that the United States would include the launch of an artificial Earth satellite as part of its role in the coming 1957–1958 International Geophysical Year.24

The Collier's series and its endless permutations is a perfect example of an event that incorporated the two basic qualities of spaceflight in culture: it not only reflected contemporary fascination with space travel (one that had been gradually growing since the 1930s); it helped fan it into a blaze. Like Verne's stories, the Collier's series also served as a self-fulfilling prediction of the future of spaceflight. It was instrumental in raising public awareness of the reality of imminent spaceflight, and it also informed a government that was about to spend many billions of dollars on a space program that it had the enthusiastic support of its taxpayers.

24. Ibid.
Today

In spite of the fact that today we are nearly 50 years into the Space Age (if one counts from the launch of Sputnik 1), there appears to be less interest in space travel than there was in 1957, or even 1947, for that matter. In fact, public enthusiasm is virtually nil—at least compared to the frenzy of the 1950s and 1960s. I believe this is largely due to the fact that we are in the midst of the Space Age and no longer at its threshold. There are few great “firsts” any more to claim newspaper headlines. There is no race upon which to base national pride. Even an extraordinary accomplishment such as that of SpaceShipOne does not result in ticker-tape parades or even children’s books and toys. Where are the SpaceShipOne table lamps, pillow cases, and cocktail coasters? It took only a few days before the story was moved to the back pages of the newspapers and probably not one person in a thousand today could tell you what the event was all about, what it accomplished, or who accomplished it.

In some ways this is good; it means that spaceflight has been accepted as a commonplace, just as flying nonstop across the Atlantic was eventually accepted. An event does not create headlines when tens of thousands of people routinely do it every day. Making spaceflight an ordinary, everyday occurrence had once been the dream of people like von Braun, but few of them thought about the price that would have to be paid. One cannot have that kind of public acceptance while at the same time maintaining enthusiasm at a high pressure. We have regular transatlantic airline flights but at the expense of not having transatlantic pilots as heroes any longer.

Will space travel ever regain the popularity it had in the 1950s and 1960s? What will it take to regain that kind of support and enthusiasm? What will capture the public imagination in the way that Wernher von Braun and the first astronauts did? Perhaps space travel needs someone as charismatic as von Braun or Carl Sagan had been—an individual upon whom the public can focus and who has the talent and knowledge to maintain and heighten that focus, to say nothing of the traits of leadership and persuasiveness. But such people are vanishingly rare.

Perhaps we need a focused space program, some specific goal that is as exciting conceptually to the general public as it is scientifically important to the scientist. There was a hint that an ember of enthusiasm for space exploration is still alive in the public breast when the Pathfinder Mars rover became one of the media heroes of 1997. For weeks, the official NASA Pathfinder Web site was receiving more hits than any other site in the world. It is no small feat for Pathfinder to have inspired some of the first space-related toys in nearly 40 years; even SpaceShipOne did not get a Hot Wheels replica. What was it about that tiny machine that so captured imaginations? Perhaps it was the image of a lone explorer—even if it was only a robot the size of a large toaster—having to fend for itself 30 million miles from home.
Since the opening of the Space Age in 1957, space exploration has become a powerful embodiment of modernity. This connection between spaceflight and modernity is so fundamental to our vision of space exploration that it no longer requires articulation or elaboration. Like many other technological legacies of the twentieth century, such as aviation, microelectronics, communications, and the Internet, space exploration represents one effective way for nations to assert their arrival on the international stage, i.e., to underscore a nation’s commitment to modernity, modernization (especially for developing nations), and ultimately, the future. In the early twenty-first century, this link between spaceflight and modernity is reinforced through cultural imagery and iconography that makes space exploration synonymous with “progress”—through exploration of new frontiers, via accumulation of new knowledge, and by bringing benefits to society. All of these associations are predicated on the fundamental relationship between spaceflight and science and technology. The scientific and technological dimensions of spaceflight—for example, the science of space trajectories and the technology of launch vehicles and spacecraft—have identified spaceflight firmly with a post-Enlightenment view of mastery over nature and “progress” in general.

How did space exploration come to be linked to modernity and, more specifically, with the discourse of science and technology? In other words, how did our collective perceptions of space exploration, as represented through popular culture, become grounded in scientific and technological concerns? This is the question I explore in this paper, focusing particularly on the Russian case.

In Russia, as in other major European nations, space travel was associated for centuries with mythology and mysticism—often in the form of dreams, parables, folk tales, superstition, or mythical tales. A fundamental shift occurred beginning only in the last decades of the nineteenth century, a transformation that culminated in the 1920s. The beginning of this change is rooted in the dissemination of the works of Jules Verne in Russia in the 1860s and 1870s and the general rise in interest of science fiction, in particular the genre of the astronomicheskii roman (or the astronomical
Partly inspired by such fictional works, the self-educated village school teacher Konstantin Eduardovich Tsiolkovskii (1857–1935) published his first meditations on the mathematics of spaceflight in 1903. Popular interest in space exploration first peaked around the time of the Great War but it was not until the 1920s—that mass interest in cosmic travel became a cultural phenomenon in Soviet Russia, embodied in the so-called Soviet space fad. It was also at this time that the idea of space travel weakened its link to mythology and superstition; helped by a vast network of scientifically minded amateur space enthusiasts, the language of spaceflight shifted into the domain of science and technology.

During the 1920s Soviet space fad, amateur and technically minded enthusiasts formed short-lived societies to discuss their interests and exchange information on space travel. These societies—the first in the world that were dedicated to space travel—operated largely without material support or encouragement from the state. The men and women who organized the cosmic societies did, of course, absorb official Marxist discourses on the role of technology as a panacea for all social ills. But the record of their actions underscores their own agency in infusing the idea of space travel (and its corollary, rocketry) with the cold, hard power of rationality, science, and mathematics. Moving from fantasy, mysticism, mythology, and lunacy, these enthusiasts appropriated the language of modernity for their case.

In this article, I revisit one specific episode in the cultural history of Soviet space exploration: the formation of the world’s first active society dedicated to the cause of space travel. In 1924, university students in Moscow formed the Society for the Study of Interplanetary Communications—“interplanetary communications” being a then-common euphemism for “interplanetary travel.” The Society sponsored lectures, established networks of enthusiasts, and wrote articles on the value of cosmic flight at a time when few had considered the possibility. Historians in both Russia and the West have described the activities of the Society in very general terms, but a lack of primary sources has prevented a fuller exploration of its significance in the early history of spaceflight. Using archival documents, my goal is not only to reconstruct the Society’s activities but also to explore the ways in which the rhetoric and activities of 1920s space enthusiasts showed a distinct appreciation for the language of science and technology. Ultimately, I hope to underscore that the relationship between the culture of space exploration and discourse of modernity was not always a given, but was grounded in historically contingent forces.

1. For a detailed description of the Soviet “space fad” of the 1920s, including an analysis of art (literature, painting, poetry, architecture, etc.) as a site for contesting visions of space exploration, see Asif A. Siddiqi, “Imagining the Cosmos: Utopians, Mystics, and the Popular Culture of Spaceflight in Revolutionary Russia,” Osiris, forthcoming.

Fridrikh Tsander

Historians typically trace the history of the Soviet space program to Tsiolkovskii, who in 1903 published the first mathematical substantiations that spaceflight was possible. In the 1920s and early 1930s, Tsiolkovskii’s original ideas on space exploration—which he republished once he discovered that others such as the Romanian-German Hermann Oberth and the American Robert Goddard had also come to the same conclusions—fed enormous popular interest in the Soviet Union in the cause of cosmic travel. Several technology-enthralled (and short-lived) societies coalesced during the period of the space fad. Of these, the most important and influential was the Moscow-based Society for the Study of Interplanetary Communications, formed in 1924. It was not only the first in the world to effectively organize for the cause of space exploration, but was also the first to build a domestic and international network around the idea. The history of the organization—a combination of serendipity, willful devotion, and eventual loss of momentum due to indifference from the state—illustrates the ways in which the technological fascinations of the day inspired a few to bring an esoteric idea to many.

No one played a more important role in spearheading the Society than Fridrikh Arturovich Tsander, who, although not a founding member, gave the Society its heart and soul. Raised in the Latvian capital of Riga, Tsander was an early devotee of the many science fiction novels of the era, and was a convert to the cause of spaceflight by the time he was 20. Unlike Tsiolkovskii, who was concerned only with the theoretical aspects of space travel, Tsander engaged in rudimentary experimentation at an early age. As early as January 1916 he built a lightweight greenhouse that would supply fresh vegetables and absorb excess carbon dioxide for travelers in space. After graduation from the Polytechnic Institute, in 1915 he started work at the Provodnik Factory, a rubber-producing facility, evidently because he believed that rubber could be used as insulating material for spaceships. Soon after the Revolution, in February 1919 he moved to the Aviation Factory No. 4 (the “Motor” Factory) where he spent his free time working on designing a new kind of aircraft equipped with an engine that could breach the atmosphere and fly into space.3

Tsander later claimed that soon after the Revolution he had personally met Lenin at a regional conference for inventors, and had told the Soviet leader about his cosmic airplane. Tsander reminisced that “Lenin made a tremendous impression on me: that night I could not sleep. Pacing up and down in my small room, I thought of the greatness of this man—our country is ravaged by war, there is a lack of bread, of coal, and the factories are at a standstill, but this man who controls this huge country

---

finds time to listen to interplanetary flights.” 4 Like many other stories of the early space years, the veracity of the meeting (which most certainly never happened) is less important than the mythic quality it conveyed. Post-Sputnik Soviet writers repeatedly alluded to the meeting to illustrate the Bol’sheviks’ interest in forward-thinking ideas at a time when the very survival of the Soviet state was in doubt. 5

Within six months of the alleged meeting with Lenin, in June 1922 Tsander quit his job at the Motor Factory to devote all his time to developing a working design of the spaceplane. He survived by the generosity of his former factory workers, who formed a pool of donations to help feed the scientist. Although they might not have shared Tsander’s unyielding belief in the possibility of space travel, they were extremely fond of Tsander; in July 1922 the chief of the production section and the chief engineer of the factory jointly wrote a formal review of his interplanetary spaceship. 6 Tsander received a certificate from the Association of Inventors for his “invention” the following month. 7 During this period of self-willed unemployment, Tsander also initiated contact with Tsiolkovskii. 8

In April 1923, after he quit his factory job to devote his full energy to his interplanetary spaceship, he thanked his coworkers for paying for his living expenses and claimed, “I hope . . . that the money which you have given me will not be in vain, but will make it possible for me to present something of value to your factory.” Going beyond pure technical considerations, Tsander genuinely believed that interplanetary flight would be for the benefit of all of humanity, thus underscoring one of the major rationales behind the popular discussions of space travel among

4. Tsander mentioned this meeting in a short autobiography he wrote in 1927 for publication in volume 4 of Nikolai Rynin’s famous Mezhplanetykh soobshchenii (Interplanetary Communications) encyclopedia published in 1929. He also gave the same account to a future coworker, L. K. Korneev, in 1932. Korneev, “Zhizni,” pp. 23–24.

7. The certificate is mentioned in Glavnauka’s letter to V. P. Vetchinkin dated 15 October 1926. See “Pismo Nauchnogo otdela Glavnauki V. P. Vetchinkinu ot 15.X.1926 g.,” in F. A. Tsander: iz nauchnogo naslediya, p. 85.

Soviet enthusiasts in the early 1920s. As an incurable utopian, he noted, “A flight around the Earth would have tremendous significance; flying like the Moon, we could use telescopes to observe the other planets much better, and could probably construct a habitation in which living conditions would be much better than on the Earth . . . .” To the factory workers, he spoke of “senior citizens [who] will find it much easier to maintain health in [space],” of the “inhabitants of Mars . . . [whose] inventions could help us to a great extent to become happy and well off,” and of “[a]stronomy, [which] more than the other sciences, calls upon man to unite for a longer and happier life . . . .”

Tsander was not a scientific dilettante; in fact, he had a masterful grasp of complex mathematics and was full of ground-breaking ideas. In his research (and in his public talks), he compared the properties of various propellant combinations and considered the heat processes, aerodynamics, and engineering behind building rocket engines. To his rapt audience, Tsander also provided details of his new spaceship, a metallic airplane that would literally devour itself as it took to the heavens. The plane would take off from land using a conventional piston engine, use its wings for additional lift until it reached a height of about 17 miles (28 km), at which point the pilot would turn on a powerful rocket engine that would accelerate the vehicle into outer space. Tsander had found that one of the most important weight penalties in designing such a spaceship would be the huge mass of fuels it would have to carry. In order to circumvent this problem, he proposed an idea, radical even today, wherein the space rocket engine would use the melted aluminum parts of its own fuselage as fuel for the engine, in combination with either liquid hydrogen or liquid oxygen. The remaining unused portion of the spaceship would then either go into orbit around Earth or fly to the other planets. He also analyzed the problems of guided reentry into Earth’s atmosphere using special wings, and various techniques of landing such a vehicle back on Earth.

The Section on Reactive Motion

Tsander had frequently spoken of trying to organize a group to study space travel. Luckily for him, public discourse on the idea of spaceflight reached a crescendo in early 1924, just as he was looking for a forum to organize. The first intense wave of public fascination with spaceflight was set off by a story “Is Utopia Really Possible?” in the newspaper Izvestiia in October 1923, about the recently published meditations on spaceflight by the foreigners Oberth and Goddard. Spurred to

promote a Russian source for such ideas, the 66-year-old Tsiolkovskii, ensconced in the provincial town of Kaluga, immediately republished his own pre-Revolutionary works under the title *Raketa v kosmicheskoe prostranstvo* (*The Rocket into Cosmic Space*), and had them distributed to bookstores and “editors and scientists” in Moscow in April of the following year, thus bringing his strange ideas about space exploration to a huge and new audience. Almost simultaneously, the Soviet media began to devote considerable attention to the cosmos. News and rumor of Oberth’s and Goddard’s exploits, the publication of Aleksei Tolstoi’s new space fiction novel *Aelita*, and the “Great Mars Opposition” of August 1924—when Mars and Earth were closer to each other than in hundreds of years—fed an unprecedented explosion public interest in space. On April 15, the newspaper *Pravda* published a long article, “Voyage Into Cosmic Space,” in which the author provided a complete history of the idea of space exploration, reaching back to Leonardo da Vinci, Cyrano de Bergerac, Jules Verne, and H. G. Wells, and bringing the story up to date with the works of Tsiolkovskii, Oberth, Goddard, and popular Soviet science writer Iakov Perel’man. Infected by the optimism of the times, the author, Mikhail Lapirov-Skoblo, concluded that “[W]ithin a few years hundreds of heavenly ships will furrow into the starry cosmos.” Three days later, *Izvestiia* published yet another article on Tsiolkovskii and Oberth, noting that Goddard had a sensational plan to launch a rocket to the Moon in the near future.

The renewed interest in space in early 1924 might have remained little more than a passing media fad had it not been for the efforts of a few dedicated individuals. Inspired by the recent publications on space travel, in mid-April 1924 students at the prestigious Zhukovskii Academy of the Air Fleet (now the Zhukovskii Military Air Engineering Academy) took action; about a dozen students from the Academy’s Military-Science Society (VNO) set up a Section on Reactive Motion to exchange

ideas about rockets. The members of the Section wrote up a short list of objectives that included the following: “(1) to unite all persons, working in the USSR on the given problem; (2) to obtain all possible information on work carried out in the West; (3) to disseminate correct information on the condition of problems on interplanetary communications, and in connection with that, publish on [such] activities; [and] (4) to [conduct] independent scientific-research work and in particular, study questions on the military application of the rocket.” Additional goals included scheduling a competition to design a small rocket capable of reaching approximately 60 miles (100 km) up into space; creating a group (kruzhok) for more in-depth theoretical study of important problems; organizing a laboratory; opening a book kiosk to “satisfy . . . the wide demand for literature”; and establishing a separate “film group” which would work on sets for films. In other words, the Section touched on all the primary dimensions that would characterize the ensuing space fad, from its technical side (building rockets) to outreach (lectures, publications, and bookstores), to building a community (by involving others interested in the same topics), to opening a channel to the West (by collecting information from overseas), and acknowledging the artistic medium as a possible way to educate and popularize (by branching into film). This Section, although only a student organization, was probably the first organized group in the world dedicated to the cause of space exploration.

The Section may have been small and without any resources, but such considerations did not limit its ambition. In enumerating a list of supplementary goals, it sought to host public reports on astronautics from serious scholars such as Vladimir Vetchinkin and Fridrikh Tsander. At the time, the 35-year-old Vetchinkin was a deputy director at the Central Aerohydrodynamics Institute (TsAGI), the leading aeronautics institution in the country. Well known nationally as a theorist of aeronautics, he also held a dual position as a professor at the Zhukovskii Academy whose students had formed the space group. Vetchinkin’s most notable research work had been on the theory of propellers but, after the Revolution, like a few

15. The leading VNO student members included V. P. Kaperskii, M. G. Leiteizen, A. I. Makarevskii, M. A. Rezunov, and N. A. Sokolov-Sokolenok. ARAN, r. 4, op. 14, d. 197, ll. 32–33. The VNO was established in 1923 with seven subsections devoted to aviation and gliding, engines, aerodynamics, scientific organization of labor, tactics, photography, and popularization. In the technical vernacular of the 1920s, Russians considered the word “reactive” or “reaction” (reaktivnyi) to represent any mode of propulsion that depended on the force of exhausted particles. Forms of reactive motion included rockets (where the vehicle carries both its fuel and oxidizer) and jets (where the vehicle carries only the fuel and uses natural air as an oxidizer). Rockets were thus capable of working in vacuum whereas use of jets was limited to inside the atmosphere.

17. Winter refers to an earlier organization, the Rocket Society of the American Academy of Sciences formed in Savannah, GA, in 1918. Little is known about the organization, which focused on rocketry rather than space exploration. Prelude to the Space Age, p. 27.
other prominent aeronautics specialists, he had begun to dabble in prognostications on space travel. Vetchinkin’s support of the Section added a critical ingredient to the Section: a patina of legitimacy.

Unlike Vetchinkin, Tsander did not enjoy a high governmental position, but there were few individuals in the Soviet Union who were more qualified to speak on the scientific and technological aspects of space travel than this 37-year-old Latvian savant. Tsander heard of the new student group on space through Vetchinkin and, although discouraged that they were not planning to immediately build rockets, quickly joined forces with them.

Having established a mandate, the Section’s first order of business was to establish contact with one man who, because of Soviet media’s search for a domestic counterpart to Oberth and Goddard, had assumed the wizened role of patron saint of the cause of spaceflight—Konstantin Tsiolkovskii. On 22 April, Moris Leiteizen, the de facto leader of the Section, composed a letter informing the old man of its recent formation, noting that 23 of its 25 members were Academy students. If Tsiolkovskii could not move to Moscow to take up leadership of the Section, then Leiteizen invited him to at least give a public talk on space travel, which they would organize at the Polytechnic Museum. In a couple of letters, Tsiolkovskii responded that he was “joyous” to hear of the creation of the Section, having already heard of its existence via newspaper reports. In poor health and terrified of leaving Kaluga, Tsiolkovskii declined the offer to visit Moscow but suggested that the Section might read excerpts to students from his recent science-fiction novel, Beyond the Earth, two copies of which he sent to Leiteizen. Less a work of literature than a dryly written polemic describing such fantastic conceptions as space suits, multistage rockets, and mooring ships in space, the novel was not known widely beyond Kaluga. Inspired by receiving the initial two copies, the Section requested the Academy administration to purchase copies of Tsiolkovskii’s books for the school library since the “demand for them was [so] great.”

Through May, the Section continued to correspond with Tsiolkovskii on various topics, although the latter’s responses often evinced a certain irritation when the young enthusiasts took action that the pioneer did not agree with. In one letter dated May 4, Leiteizen informed Tsiolkovskii that one of the immediate goals of the Section was to “study reactive engines, independent of their application . . . [and] in

18. For background to Vetchinkin, see A. M. Tarasenkov, “29 iunia—100 let so dnia rozhdeniia V. P. Vetchinkina (1888 g.),” Iz istorii aviatsii i kosmonavtiki 59 (1989): pp. 59–64. One of the initial organizers of the Section, Georgii Kramarov, notes that Vetchinkin was “one of the first” to support the group. Kramarov, Na zare kosmonavtiki, p. 12.

19. Leiteizen to Tsiolkovskii, 22 April 1924, ARAN, f. 555, op. 4, d. 356, ll. 1-106b.

20. For Tsiolkovskii’s four letters to the Section in 1924, all addressed to Leiteizen, see ARAN, f. 444, op. 3, d. 102a, ll. 1–2 (April 29), ll. 3–4 (May 14), l. 5 (May 31), and l. 6 (June 4).

order not to complicate [matters] . . . use them in the most simple form of motion on the Earth’s surface: in a reactive automobile.” Tsiolkovskii tersely replied that “[I]t’s known that reactive automobiles . . . are playthings and won’t provide anything new to you.” Despite the often strained communications, members of the Section clearly considered Tsiolkovskii some sort of spiritual guide whose works could convert the uninitiated, not just in the Soviet Union but everywhere, to the cause of space exploration. On behalf of the Section, Tsander wrote to Tsiolkovskii on 16 May, asking for permission to translate Tsiolkovskii’s classic works from 1903, 1911, and 1914 into German. Amazingly, the old pioneer replied that although he was “grateful,” he could not provide original copies of the said publications since he had no copies left. Tsander, unable to find the originals, did not translate them, significantly limiting Tsiolkovskii’s reach beyond the Soviet Union.

“HOW MODERN SCIENCE AND TECHNOLOGY SOLVES THIS QUESTION”

The Section’s first public task was to organize a lecture. In picking a first speaker, the members of the Section not only looked for someone with authority but also an individual who would dispel the notion that space travel was a fantasy. The Section students invited one Mikhail Lapirov-Skoblo, a propitious choice since he was personally acquainted with Lenin. An engineer by education, Lapirov-Skoblo had been part of the pre-revolutionary technical intelligentsia but was also one of the first of that demographic to wholeheartedly put his faith behind Lenin’s vision of a modern Russia. In the early 1920s, Lapirov-Skoblo was the deputy chairman of the Scientific-Technical Department of the Supreme Council of the People’s Economy (VSNKh or Vesenka), a job that put him in charge of intellectuals who were engaged in introducing modern technology to the Russian economy. When Lenin supervised the formation of the State Commission for Electrification of Russia (GEOLO) in 1920, Lapirov-Skoblo was tapped to represent the Vesenka on GOELRO. His many other ad hoc duties included service as head of the Department of Science and Technology of the newspaper Pravda. Having read Tsiolkovskii’s recently published works, Lapirov-Skoblo wrote the first comprehensive expositions on the topic in the post-Revolutionary era in

23. Tsiolkovskii to Leiteizen, 14 May 1924, ARAN, f. 555, op. 3, d. 102a, ll. 3–4.
24. Tsander to Tsiolkovskii, 16 May 1924, ARAN, f. 555, op. 4, d. 670, ll. 4–5.
25. Lapirov-Skoblo was also a member of the collegium of the Electrical Industry Association, an academic, a member of the State council, and member of the collegium of the People’s Commissariat of Communications. For biographies, see ARAN, r. 14, op. 14, d. 197, ll. 30–30b; Kramarova, Na zare kosmonavtiki, pp. 22–23.
*Pravda* and other publications in 1924. In the waning days of May 1924, members of the Section put up posters at various key intersections in Moscow proclaiming that Lapirov-Skoblo would give a talk on “Interplanetary Communications” (“How Modern Science and Technology Solves This Question”); the paid lecture would begin at 8:00 in the evening on Friday, 30 May at the main auditorium of the Polytechnic Museum. All monetary contributions would go to fund a laboratory for the Section.27

The event was successful beyond all expectations. Tickets sold out two days before the event; on the day of the lecture, the Museum’s administrators were forced to call for the police to control the mass of people who had arrived to attend. All the literature on space travel that the students had on hand to sell—Russian editions of H. G. Wells’s *War of the Worlds*, Russian science fiction from Aleksei Tolstoi and Aleksandr Beliaev, and books by the popular science writer Iakov Perel’man—had been sold out in minutes. In total, the group amassed 2,500 rubles—an astronomical amount for the time. Lapirov-Skoblo’s lecture, quite possibly the first talk on space exploration in Russia open to the general public, consisted of a short history of rocketry and space exploration.

Lapirov-Skoblo approached the idea of space travel much like one would treat an arcane discussion on any branch of science or technology. He considered the different technical options for reaching space, methods of propulsion, and the choice of propellants. At the same time he also linked the promise of space travel with the future modernization of the Soviet Union, grounding his words into a narrative that privileged national development over universal significance. Like many others of the period, he took pains to emphasize that the Russian Tsiolkovskii had done decades earlier what the foreigners Oberth and Goddard were only doing now. Yet Lapirov-Skoblo was also generous to the Westerners. Using hand-built models, he explained to the rapt audience the characteristics of multistage rockets and spaceships proposed by Oberth and Goddard. On the latter, Lapirov-Skoblo was less confident that the American would be able to launch a rocket to the Moon, given the vast technical difficulties of such a project. He ended his lecture by calling on Soviet populace to focus on a more immediate goal, to build rocket engines in order to “transform into reality the centuries-old dream of flight into space.”28

27. For a reproduction of the poster, see Kramarov, *Na zare kosmonavtiki*, p. 23.

28. The complete text of Lapirov-Skoblo’s lecture is stored in ARAN, r. 4, op. 14, d. 194, ll. 49–62. For recollections of attendees, see ARAN, r. 4, op. 14, d. 197, ll. 35–38; Kramarov, *Na zare kosmonavtiki*, pp. 25–28.
The Society for the Study of Interplanetary Communications

After the lecture Section members informed the audience that they were intent on expanding the Section into a larger Society for the Study of Interplanetary Communications (Общество изучения межпланетных сообщений, or OIMS) not limited to Academy students but open to the general public, and invited audience members to sign up. As a result, 179 people from the audience put their names on a list. Of the 121 names preserved in the archives, 104 were men. The majority of the members (about 60 percent) were young, between the ages of 20 and 30; most of the rest were either teenagers or in their 30s. The signatories were also asked to list their professions. A total of 96 members (roughly 80 percent) were evenly split between being students and workers. A smaller number identified themselves as “scientific workers,” “writers,” and “scientists and inventors.”

We know some personal details of these young men and women. Of the Zhukovskii Academy students, the most active was 27-year-old Morris Leiteizen, the son of the old Bolshevik, G. D. Lindow-Leiteizen, who was killed in 1919 on the eastern front. The Leiteizen family lived with the exiled Lenin in Finland before the Revolution. After the October Revolution, Leiteizen worked briefly in the People’s Commissariat of Foreign Affairs in Finland before opting to come back to Russia to fight in the Civil War. On the way back from Helsinki, Leiteizen was arrested by the White Finnish imperial forces and thrown into prison in Helsinki. Lenin took a personal interest in the matter, and only after a series of diplomatic moves did the Finnish free the near-dead prisoner. Leiteizen, who was fluent in German, French, and English, had been interested in astronomy since his youth, and, according to a contemporary, believed that space travel was “a matter of the relatively near future.”

The rank-and-file members included V. S. Berdichevskii, only 17 years old; V. L. Pul’ver, the son of a well-known musician-composer, Anatolii Beliaev, who managed a local astronomical observatory; and Nataliia Sysoeva, a young assistant who worked there. Then there was Valentin Chernov, a young musician apprentice so taken by reading the works of Tsiolkovskii that he had visited the old man in Kaluga. Unable to decide between a career in music or space travel, he had decided to do both. He enrolled in a university to get a degree in astronomy while working part-time as a violinist at the Bol’shoi theater.
Some Society members, including theorist Tsander, popular science writer Perel’man, and Academy professor Vetchinkin, were part of the pre-Revolutionary technical intelligentsia, i.e., they were older than the main body of members but still young enough to have been energized by the possibilities opened up by the Revolution. Vetchinkin provided the necessary institutional backing; Perel’man served as a conduit to the media, and Tsander represented the spiritual nexus for the group’s activities. The de facto leader of the Society, however, was Grigorii Kramarov, a 36-year-old Comintern worker who had had a long history of active work on behalf of revolutionary causes. In January 1905 he was arrested by the Tsarist police for his illegal activities—the first of six times he was incarcerated for a variety of revolutionary activities on behalf of the Russian Social Democrats. After his last arrest in February 1913, Kramarov fled Russia and escaped to the United States. During the four years he lived in San Francisco, he worked at a fabric factory and actively participated in the Russian section of the American Communist Party, and was also a member of the Committee to Aid Political Prisoners and Exiles in Siberia. Hearing of the February 1917 revolution, Kramarov immediately returned home to work with the Mensheviks. Following active duty with the Fifth Army on the eastern front during 1919–1920, Kramarov worked abroad for Comintern before returning to the Soviet Union.33

The Soviet media were surprisingly attentive to the work of these men and women and, with a few exceptions, journalists favorably reported on their activities. Vecherniaia izvestiia (Evening News), a widely read evening newspaper, and the journal Iskra (Spark) gave prominent space to the Society’s structure, goals, and members. The former underscored that the Society’s activities were not divorced from the masses, whereas the latter emphasized that Tsiolkovskii’s and Goddard’s work gave, for the first time, hope to bridge the gap between aspiration and achievement.34 The biweekly Tekhnika i zhizn’ (Technology and Life), one of the most popular science journals of the day, published a special issue in July 1924 dedicated to interplanetary travel; its cover story on the OIMS included a picture of Kaperskii, Rezunov, and Leiteizen in Academy uniforms, huddled over their documents. The author of one article, A.A. Mikhailov, the director of the Pulkovo observatory, introduced his readers to the elementary concepts of rocketry and space exploration and Tsiolkovskii’s various spaceship designs. He singled out Tsander’s scientific contributions to the field. In another article, “The Rockets of Goddard and Oberth,” Ia. Gol’berg provided illustrated summaries of various Oberth projects, including a “passenger

34. Vecherniaia izvestiia issues for 25 June and 7 July 1924. These articles are preserved in ARAN, r. 4, op. 14, d. 194, ll. 115–116.
rocket,” a “station in space,” and Goddard’s alleged Moon rocket. Other articles in the issue dealt with the biology of high-altitude flight, long-distance aviation, and “superguns.” The issue was illustrated with detailed artists’ impressions of rockets and spaceships taken without attribution from the popular American science magazine *Science and Invention*.

### The Society’s Work

Having formed the core of the Society, the members now set out to define precisely what they wanted to do. On 20 June 1924 the OIMS held its first official organizational meeting in the auditorium of the astronomical observatory of the Moscow region’s Department of National Education (MONO). About 200 people filed into the relatively small hall adorned with portraits of Newton, Kepler, Herschel, Bredikhin, and other renowned scientists. The three main organizers of the event, Leiteizen, Kaperskii, and Rezunov, sat at the main podium. As the first order of business, all assembled unanimously elected two men as honorary members of the Society: Tsiolkovskii, the founding father of Soviet rocketry, and Perel’man, the most important publicizer of the cause of spaceflight.

The meeting then led into a spirited discussion over the future goals of the Society. Using the blueprint of the smaller student Section of a few months earlier, the OIMS drew up a six-point charter (устав), the first point of which was to “work on the accomplishment of extra-atmospheric flight with the aid of a reactive vehicle.” Knowing that such an ambitious goal was out of the immediate reach of the Society, members emphasized more immediate activities like its predecessor Section, such as establishing a network of people all over the Soviet Union interested in the science of interplanetary travel, collecting data from the West, and most important, disseminating “reliable information” to the “broad masses” by way of “lectures, reports, organizing libraries, exhibitions, publishing scientific and popular literature, both original and translated.” Outreach and publicity were central to the Society’s mandate and crossed over international barriers: the members decreed that one of their main goals would be to contact Goddard and Oberth and translate into Russian their respective 1919 and 1923 monographs. At the end of the meeting,

36. Compare the illustrations on p. 11 and the inside cover of *Tekhnika i zhizn*’ issue with those from Don Home, “Can We Visit the Planets?” and Raymond Francis Yates, “Picture of the Earth,” both in *Science and Invention* 11 (February 1924): pp. 962, 977.
37. “Ootchet ob organizatsionnom sobranii OIMS,” ARAN, r. 4, op. 14, d. 196, l. 1.
38. “Ustav obshchestva mezhplanetnykh soobshchennii,” ARAN, r. 4, d. 196, ll. 2–3.
all the members voted to elect a central body of the OIMS, the “presidium,” that included Tsander, Leiteizen (secretary), Kaperskii, Rezunov, Chernov, Veigelen, and Kramarov. For the time being, the Society’s home base would be the MONO astronomical observatory.

Kramarov, who was chosen to chair the presidium, recalled 40 years later that no one had any illusions that they would soon be sending men into space. He remembered that “[I]n the work of the Society [they] all saw one more possibility to aid the Motherland, to aid in the building of socialism.” They would do this not by actually building rockets, but by bringing science to the masses. They were “convinced that the Society’s work would contribute to the preparation of cadres, who in the future would create the economic and scientific and technical base for solving the greatest problems.”

Like many utopians of the day, they justified their actions by establishing the most tenuous of connections with the exigencies of the new Soviet state. The technological fascination of the era provided a perfect bridge to connect utopian dreaming with real problems.

The OIMS was officially divided into three thematic sections, which loosely reflected its activities: a scientific-research section to do experimental work; a literature and propaganda section to publish the work of the Society; and a scientific-popularization section to organize lectures at various institutions.

Because of limited funds, the Society produced little in terms of technical achievement—the goal of their first section. During its lifetime, there was no unanimous agreement on the clear distribution between performing “real” science and doing outreach at the OIMS. Tsander, one who frequently let his enthusiasm exceed his reach, most passionately believed that the members should immediately move to scientific and engineering work. No one in the Society, however, had the slightest idea of how to cultivate practical work. In this vacuum, Tsander took control. In a report to the Society’s “board of directors” (pravleniia) on July 15, he asked rhetorically “How can we perform our investigations, what should we undertake first . . . ?” He laid out a four-point plan that would begin with “laboratory work” and end with the “construction of a large vehicle to lift men into the higher layers of the atmosphere and interplanetary space itself; we hope we will be able to shake hands on other planets.” His detailed laboratory plan included considerations on testing small rockets, researching the various dimensions of rocket design; designing and cooling fuel tanks and engines; ideas on propellant selection and metal selection for the body of the rocket; exhaust gas dynamics; designing
ground systems to test rocket elements; and developing life support and electrical systems. He seemed to believe that the Society’s announced contest to develop a rocket “would advance [their] work greatly.” Unfortunately, despite talk of closely coordinating theoretical, design, and experimental work, there is no evidence that the OIMS actually established a laboratory for such tasks.

The second section’s ambitions also outstripped its material limitations. In May, leading member Leiteizen invited Tsiolkovskii in a letter to contribute an article for a new monthly journal which they would call Raketa (The Rocket). Their plan was to publish serious works on interplanetary travel and related fields such as astronomy, physics, chemistry, and aeronautics. Since they were unable to find any publishers interested in issuing such a journal, the members had planned to use money collected from both the Lapirov–Skoblo talk and from book sales. Tsiolkovskii offered the first part of his “Life in the Cosmic Ether” for Raketa. Others, including Tsander (“On a Flight Over Other Earthly Spheres”) and Vetchinkin, as well as OIMS member Rezunov (“The Dream of Humanity”) wrote additional articles. Society member Mozharovskii prepared an evocative cover of a rocket flying over a planet with a background of galaxies and stars. In the end, no journal was published. Kramarov remembers that they were unable to “overcome many difficulties, especially insufficient money.” Members collectively sent a letter to a major newspaper, asking to have an announcement published, free of charge, explaining that the Society had books and information on space travel for sale at their home location at Bol’shaia lubianka street. The newspaper declined to publish the letter.

The OIMS was more successful disseminating ideas about space travel via lectures. At a meeting on June 30, the scientific-popularization section rejected section head Serebrennikov’s suggestions for public presentation topics on specialized topics, and instead voted to have talks that would appeal to a very general

audience, with a focus on history and forecast. However, few in the Society beyond Tsander knew anything about rocket engine design. In late July, Tsander gave a talk to the OIMS’s scientific-popularization section, the first part of which dealt with the history of visions of space travel, and the second part on the mathematics of rocket velocities, complete with differential equations. By teaching the Society’s own members something of both the past and the possibilities of space exploration, Tsander not only helped to disseminate ideas about the “correct” way to space, i.e., with liquid-propellant rockets, but also inculcated his young audience with the idea that three men, one Soviet (Tsiolkovskii), one German–Romanian (Oberth), and one American (Goddard), were the true founding fathers of the theory of spaceflight. He helped to establish a pantheon—a holy trinity—for a new scientific era that has endured to the current day.

**Mania Over Goddard**

The Society not only maintained regular contact with Tsiolkovskii through its existence, but also communicated with the reclusive American rocket scientist Robert Goddard. Society records reveal that in response to an inquiry from Leiteizen, the American wrote to the Society on 16 August 1924, expressing pleasure at the formation of the Society and indicating that he would be interested in cooperating with them. At one of the major talks in Moscow in early October, Tsander read Goddard’s letter to the audience. Goddard had also sent the Society a copy of one of his recent articles published in the journal *Monthly Weather Review* wherein he conjectured on the velocity required to send a rocket to the Moon; the Society quickly translated the article into Russian for its members, thus providing one of the most influential sources of information about Goddard’s work in the Soviet Union for many years.

Garbled press reports alleging that Goddard was planning to launch a rocket to the Moon fostered a mini-mania among space enthusiasts all over the Soviet

51. Goddard to OIMS, 16 August 1924, ARAN, r. 4, op. 14, d. 195, l. 16. For the sent version of the Goddard article and its Russian translation, see ARAN, r. 4, op. 14, d. 194, l. 44–45. The article was “The High-altitude Rocket,” *Monthly Weather Review* 52 (February 1924): pp. 105–106.
Union. Original reports had suggested that Goddard would launch a rocket to hit the Moon on 4 July 1924. But in mid-June, the science reporter for *Izvestiia* noted that according to *The New York Herald*, Goddard had postponed his launch to August 1924. As summer turned to fall and there was no news, Goddard fever reached such proportions that the city police once had to be called out in Moscow. Responding to the notoriety over the alleged Goddard shot, the Society asked a prominent Leningrad-based astronomer, V. V. Sharonov, to speak to the public on the Goddard project at the Main Hall of the Physics Institute of the Moscow State University. The Society printed up artful posters under the giant headline “Polet na drugie Miry” (“Flight to Other Worlds”) which were put up at several major intersections in Moscow. Sharonov gave two separate lectures, both on the first day of October 1924: “The Truth on the Dispatching of Professor Goddard’s Projectile to the Moon on 4 August 1924” and “Debates in the West in Connection with Sending a Projectile to the Moon.” At 8:00 p.m. on the night of the talk, so many people showed up that the Moscow horse militia had to be called out to control the crowds who were unable to enter the auditorium. All the tickets, for 30 kopecks each, had been sold out. Due to popular demand, the Society asked Sharonov to repeat the talks—this time followed by public debates—on 4 and 5 October.

Society-organized debates, such as the one on Goddard, were quite common in the fall of 1924. Some were limited to the membership, such as the one on “Cosmogony Hypotheses” by member V. S. Berdichevskii on September 24. Others were open to the public for a small fee—about 30 kopecks. Usually, these public lectures had two components, a first talk by a distinguished guest and then a second talk and open debate (disput) on a controversial topic. For example, the Society held highly publicized lectures at the Russian Polytechnical Museum on 31 October and 2 November, this time by Vladimir Vetchinkin, the Zhukovskii Academy professor and aeronautics expert who had helped to establish the Society. His two-part lecture, beginning each night at 8:00 p.m., covered both the popular and mathematical aspects of interplanetary travel. Later, the Society’s own Vladimir Chernov gave a talk on “Construction of Rockets,” followed by debate on the best way to do so. Those who paid the 75 kopecks to 3 rubles (depending on the seat) were privy to see not only Vetchinkin and Chernov but also to hear spirited discussion among representatives from the Moscow Society of Amateur Astronomers, Glavvozdushflot (the civil air fleet), the ODVF (a voluntary society for aviation enthusiasts), Dobrolet (Soviet airline), and the journals *Vestnik vozдушного*

53. For a reproduction of the poster for 4 October as well as Tsander’s comment about the “horse militia,” see Korneev, “Zhizni’,” pp. 29–30. See also Kramarov, *Na zare kosmonavtiki*, pp. 54–55. Tsander also gave talks on all three days.
flota (Air Fleet Bulletin) and Samolet (Aircraft). Their attendance was critical because it gave these often-bizarre proceedings the implicit stamp of official sanction; ODVF and Dobrolet were important elements in the Soviet government’s drive to inculcate a young post-Revolution generation with up-to-date technology by equating aviation with modernity. If some in the press and elsewhere were tempted to derisively speak of the “youth who believe in such fables,” others took pause and infused the talk on spaceflight with a certain sense of gravitas. Lectures elsewhere in 1924—at a number of aviation factories, at the Bauman Higher Technical School, and at the Shternberg Astronomical Institute—also expanded the sites of discussion. Society representatives, including Sharonov, Prianishnikov, and the indefatigable Tsander, took their message outside of Moscow in 1924–1925 to give talks in such disparate locales as Kharkov (on 17 October), Leningrad (on 17 November), Tiazan (in November), Tula (in December), and Saratov (in January 1925). The Society archives contain letters from enthusiasts in places as far away as Zlatoust and Kharkov, expressing their wish to engage in joint work on interplanetary travel.

The Society and the Arts

The Society produced no work of art or literature but, during its brief existence, its members actively discussed and helped to popularize space-themed artistic works of others. For example, their interest in space travel was catalyzed by a number of famous science-fiction novels such as Aleksandr Bogdanov’s Krasnaia zvezda (Red Star, 1908) and Aleksei Tolstoi’s Aelita (1923). The former, the first major Russian work in the genre of science fiction to deal explicitly with spaceflight, was written before the Revolution but was widely read and discussed afterward. Bogdanov (a pseudonym for Aleksandr Malinovskii) had had a much-publicized split with Lenin, but his popularity in the 1920s, which rested on Red Star and his other science-fiction novel Inzhener Menni (Engineer Menni), did not suffer. Reprinted in 1918 and 1929, Red Star was not, of course, about spaceflight, but about an

54. The Moscow Society of Amateur Astronomers (MOLA) was represented by its chairman A. A. Mikhailov, Dobrolet by engineer Kh. I. Slavernov, and Samolet by pilot S. I. Pokrovskii. See the poster for the talk in Kramarov, Na zare kosmonavtiki, p. 53. Glavvozdukhoflot stood for Main Administration of the Workers’ and Peasants’ Red Military Air Fleet, i.e., the Soviet “air force.” ODVF stood for Society of Friends of the Air Fleet.

57. For a detailed description of the artistic dimensions of the “space fad,” see Siddiqi, “Imagining the Cosmos.”
idealized communist utopia on the planet Mars; some have seen Bogdanov’s tale as a warning on how socialism would take on distinctly totalitarian tones if sufficiently militarized.\(^5^9\) In constructing a future administered by a “benevolent technocracy,” Bogdanov articulated an explicitly technologically utopian vision that seemed to coincide much more with the prevailing feeling of the 1920s than the pre–World War I period when he wrote the novel.

After the Revolution, when *Red Star* was especially popular among the reading public, the novel resonated deeply with the space enthusiast community who shared Bogdanov’s utopian notion that modern technology, especially space technology, could remake society in unimaginable (and positive) ways. At the height of the space fad in 1924, Society for the Study of Interplanetary Communications secretary Moris Leiteizen wrote to Tsiolkovskii, announcing that they were in communication with Bogdanov; among other things, they were particularly interested in Bogdanov’s rather unusual proposal to use atomic power to propel his apocryphal spaceship.\(^6^0\)

The novel’s lasting relevance for space enthusiasts is underscored by a review of the book published in 1934 by spaceflight popularizer Nikolai Rynin, who gushed (incorrectly) that Bogdanov was the first to predict the use of nuclear power for spaceflight.\(^6^1\) In general, space enthusiasts were less likely to explore Bogdanov’s philosophical arguments than his technological vision; both parties shared a view of technology as autonomous, positive, and liberating.

The space enthusiast community had a similar take on the most famous Soviet science–fiction novel of the 1920s, Aleksei Tolstoi’s *Aelita: Zakat Marsa (Aelita: Sunset of Mars)*, first published in serialized form in 1922–1923.\(^6^2\) Much has been written about the novel, which is about an engineer’s and a soldier’s trip to Mars, the latter of whom incites a proletarian revolution in a bourgeois social setting. Aelita is the queen of Mars who falls in love with the Red Army solder. Superficially, *Aelita* has all the elements of post–Revolutionary utopian science fiction: a bourgeois enemy, a Marxist revolution, the most modern science and technology of space travel, adventure and romance borrowed from Edgar Rice Burroughs, and a utopian theme. Yet, as Halina Stephan has pointed out, the novel is also characterized by mysticism and by “themes borrowed from the theosophic and anthroposophic

---

60. Leiteizen to Tsiolkovskii, 4 May 1924, ARAN, f. 555, op. 4, d. 356, ll. 2–3.

mythology.”

The immediate reaction to the novel was rather negative since many of the more ideologically active Bolsheviks viewed *Aelita* as a novel with an ambiguous pro-Soviet message—the Revolution on Mars had, after all, failed. Yet, the technologically-minded spaceflight enthusiasts found it inspiring: Tolstoi’s novel was the first major Soviet novel of the period that used a rocket for interplanetary travel—a key aspect that attracted the attention of many. For example, the Society for the Study of Interplanetary Communications was so taken by Tolstoi’s use of the rocket that they considered using the story to develop a film script, a project that was brought to fruition by others.

In terms of film, the seminal *Aelita* (1924) and the lesser-known *Kosmicheskii reis* (*Space Voyage*, 1935)—the two movies which bookended the Soviet space fad—were the only film projects that reached fruition, but they were not the only attempts to bring cosmic voyages to the screen. In 1924, the Society informed Tsiolkovskii that they had contacted Proletkino, the official Soviet movie-making authority, with the idea to develop an original film script. Tsiolkovskii insisted that the Society write a script for his novella *Beyond the Earth*, but Society representative Moris Leiteizen responded that they would rather not use that pre-Revolutionary story: “We have decided to give our film some lively character: the action should take place in our day in Soviet Russia.” The Society produced two scripts, both extraordinary not for their artistic merit but because they astutely mirrored the concerns of the Society.

Member M. G. Rezunov’s four-part script closely followed Tolstoi’s *Aelita* with a Martian character named Le (Tolstoi’s hero was named Los’), but added an odd twist near the end. The action is initiated when Stepan, a factory worker, reads about Goddard’s plan to launch a rocket to the Moon on 4 July. Gripped by the idea of spaceflight, Stepan devises a plan for a spaceship which, after presentation to the ODVF (the voluntary aviation society), the Society decides to build. The central intrigue of the story involves a “foreign” spy who disrupts the construction work. The obligatory voyage to Mars is embellished by scenes of life in space, the hazards of meteorites, befriending a Martian communist, and ultimately a return trip in which Stepan, unable to live without Le, decides to commit suicide by exiting his ship and becoming an Earth satellite. Stepan, it seems, would rather be dead in space than alive on Earth.
Society chief Grigorii Kramarov’s script was a brilliant synopsis of many of the tropes of the space fad. The action begins in the late Tsarist era when the imperial government forbids any talk of space exploration. A Russian revolutionary inventor, modeled on the great martyred “spaceship inventor” Nikolai Kibal’chich, produces a plan for a rocket ship. He is arrested and executed, but not before bequeathing his plan to his young son, Viktor, who like his father, links the struggle against the autocracy with the struggle against gravity. With his plans and dreams in hand, the young revolutionary moves to the United States to fulfill his father’s dream of spaceflight. With the help of likeminded others in America, Viktor begins building the rocket ship when a rich banker discovers the project. The banker decides to build his own ship and asks Viktor to join his company. Angry with Viktor’s refusal, the banker seizes Viktor and his model and takes them to his villa, where he employs a team of engineers to finish the design. The banker’s daughter, of course, falls in love with Viktor and helps him escape the depths of the banker’s capitalist hell. Viktor’s industrious American friends convince him that he must return to Russia, for there is a Revolution underway at home. The young man, disguised as an “engineer-expert,” manages to free his vaulted ship and fly the rocket-machine to Russia where, upon landing, he is greeted with much fanfare to “start the victory over the cosmos!” Here we find the patron saint (the Kibal’chich archetype), the equation of gravity with oppression, America as a place where technological dreams come true (especially if capitalists get out of the way), and the all-encompassing myth of Bolshevik recognition of the value of spaceflight—all in one film. Although the Society approached several major studios to finance the project, including Proletkino and Mezhrabpom-Rus’, they found no one to produce the movie.

Even though, in 1924, Soviet filmgoers were deprived of the pleasures of watching Stepan and Viktor on screen, they might have seen the most famous Soviet science fiction in the prewar era, Aelita, the movie version of Tolstoy’s book about a voyage to Mars, directed by the famed pre-Revolutionary Russian director Yakov Protazanov. The silent movie, which was released officially on 25 September.

68. Kibal’chich was a member of the People’s Will terrorist organization which assassinated Tsar Aleksandr II. Before his execution in 1881, Kibal’chich devised a plan for a rocket-propelled vehicle that later Soviet historians absurdly claimed was an early design for a spaceship.

70. “Vospominaniiia Kaperskogo,” ARAN, r. 4, op. 14, d. 197, l. 41.

1924 at the peak of the space fad, contributed enormously to the popularization of spaceflight in Soviet culture in the 1920s. It is no coincidence that space enthusiasts such as the OIMS enjoyed their highest attendance ratings at talks soon after the movie was released.

Protazanov’s goal to produce an “impartial” work was not rewarded in like. Despite widespread criticism of the film—many complained about the fact that the revolution on Mars had failed—it was an incredibly popular film; it did, after all, feature dramatic acting, an exotic planet, a glamorous princess, and a romantic story arc. Grigori Kramarov, the head of the OIMS, effusively remembered years later that “[T]he book and film played a significant role in strengthening interest towards interplanetary communications and contributed to the development of activities of our Society.” The movie made a deep impression on many young people. Vladimir Chelomei, who was only 10 years old when the film came out, 45 years later named his dream project—a huge space complex to send the first Soviet cosmonauts to Mars—Aelita.

**The Society’s End**

In the end, lack of financial and governmental support proved to be the Society’s undoing. Most Russian sources note vaguely that the Society existed for “approximately a year” and then disbanded. In reality, the Society probably dissolved long before a year was over. Society secretary Leiteizen wrote to Tsiolkovskii on 16 December that the Society was “currently in a period of liquidation.” As an explanation, he noted, “[I]t’s not so terrible that we hurried, but we ran ahead [of ourselves by] several years, only to come back to the present.” He added in resignation, “I’m also inclined to think that such a noisy Society was excessive: we can still work splendidly for now without a Society. And [perhaps] even work better.”

Why did the Society fall apart so soon after the successful lecture series in October and November? The most important factor was lack of official state recognition. Although the Society was sponsored by the Moscow Society of Amateur Astronomers (MOLA) and the Military-Scientific Society (VNO) of the Zhukovskii Academy, it was never an officially recognized organization. In late 1924, when the Society petitioned the administrative department of the Moscow

Making Spaceflight Modern: A Cultural History of the World’s First Space Advocacy Group

city council to officially register the organization, the city council rejected the application on grounds that the Society had “insufficient scientific strength among its members.”76 Probably the most fatal blow for the Society was that its patron, Academy Professor Vetchinkin, declined to formally become a member, thus depriving the group of legitimacy in the eyes of both the Academy and the Soviet security services who had to sign off on any formal social organization in the Soviet Union.77 The following year, Tsander confirmed that the lack of “scientific workers” among members of the “board of directors,” i.e., Tsander, Leiteizen, Kaperskii, Rezunov, Chernov, Serebrennikov, and Kramarov, was a source of dissension that contributed to the Society’s dissolution.78 The members unsuccessfully appealed the city council decision and were dealt a second blow when, upon hearing of the city council’s decision, the Military-Scientific Society withdrew its support of the Society.79 Soon after, the enthusiasts abandoned their efforts.

The Society’s members also had deal with less-committed members who were unable to sustain interest in the face of both financial insecurity and the possibility that space exploration was decades away. Society head Kramarov remembers that the most common question from the audience after each lecture was “How quickly would flight to the planets be accomplished?”80 Tsander’s naïve and unbounded optimism that interplanetary travel was imminent raised the hopes of many who had no idea of the incredible technical difficulties. When it became clear that travel into space was years (if not decades) away, the “accidental members” dispersed quickly, leaving only a handful of the truly dedicated to pursue the cause.81 And eventually even the faithful had to come down to the ground; most, such as Tsander, had little time to devote to activities that did not provide money for living. Chernov, for example, remembered later that his job as a musician forced him to abandon the Society.82 Because the group was never officially recognized or registered by

any state authority, it never received any funds from the state and maintained its activities by donations or from ticket reimbursements. And once the members were unable to register the Society with official authorities, the two major institutions that sponsored the Society, the MOLA and the VNO, cut off their modest support.

Few members of the Society for the Study of Interplanetary Communications went on to participate in the practical development of rocketry funded by the Soviet government in the 1930s. The notable exception was Fridrikh Tsander, who in 1931 founded the Group for the Study of Reactive Motion (GIRD), the semi-amateur team that launched the first Soviet liquid-propellant rockets in 1933. Tsander served as a crucial link between the Society and the most important personality of the early Soviet space program, Sergei Korolev. Tsander’s unexpected death in 1933 from poor health was a deep blow to Korolev. In the heady days after the launch of Sputnik in 1957, Korolev searched out Tsander’s grave to set up a special memorial in his name.

Others from the 1924 Society for the Study of Interplanetary Communications fared worse, especially the ones who fell at the height of the Stalinist Great Terror in the late 1930s. On 16 April 1939, the NKVD (the Soviet security services) shot former Society secretary Morris Leiteizen—then 42 years old—because he was the son of an old Bol’shevik. Mikhail Laprov-Skoblo, one of the earliest advocates for spaceflight in the 1920s and the man who gave the first rousing lecture to recruit members for the Society in 1924, also fell to the purges. After a very distinguished career as a vocal spokesperson for the Soviet scientific and technical intelligentsia, he was arrested in 1937, sentenced in 1941, and died in confinement in 1947 while working at a factory.83

CONCLUSIONS

The Society for the Study of Interplanetary Communications was the world’s first organization dedicated to the study of spaceflight. Besides its claim to priority in the history of space exploration, the organization left behind two important legacies.

First, the Society—with the help of enthusiastic Soviet media—wrenched space travel from the discourse of fantasy and relocated it into the language of science and technology. Prior to the 1920s, in the public imagination space exploration was considered in the same breath as mythology, speculation, and mysticism. In the 1920s, by linking spaceflight with the sciences (mathematics, chemistry, metallurgy, etc.) and suggesting that space travel was possible by means familiar to most people (such as rockets), the spaceflight advocacy community brought such ideas into the realm of reasonable scientific prognostication.

Second, by underscoring the scientific and technological bases of cosmic travel, the community equated spaceflight with “being modern.” Space advocates fit their conception of space travel firmly within the Bol’shevik cause of remaking Russia into a modern, technologically capable nation. After the 1920s, spaceflight was, like aviation, a manifestation of the self-reflexive notion of twentieth-century modernity. The equation of spaceflight with science and modernity meant that space travel was now connected not only with the past—such as the Russian Cosmist philosophy which was committed to reanimating the dead by exploring space—but also with the future.84 Mystical ideas like Cosmism were rare among space enthusiasts of the societies and exhibitions of the 1920s, which favored a fetishistic view of technology in general and space travel in particular. This fetishism, bordering on messianism, is profoundly evident in the works of the Society—particularly in the language that they used, the goals that they set out to accomplish, and the way in which they saw technology as a panacea for many if not all social ills. Writing of the Soviet Union in the 1920s, Anthony J. Vanchu notes that “[W]hile science and technology had the power to demystify religion and magic, they themselves came to be perceived as the locus of magical or occult powers that could transform the material world.”85 This kind of stance toward space travel is not so very different from the visions of space enthusiasts in entirely different social contexts, such as in the United States; many American activists also adopted an almost evangelical view of human migration from Earth into outer space—one that was not only inevitable but essential for the survival of the species.86 The Society for the Study of Interplanetary Communication was perhaps the first organized attempt to articulate this singular vision of space travel which has continued to play an important role in those who believe—misguidedly or not—that through the power of science and technology, humankind will attain its rightful destiny in the deeper reaches of the cosmos.

C/SETI as Fiction: On James Gunn’s
The Listeners

De Witt Douglas Kilgore

Over the past four decades the search for extraterrestrial intelligence (SETI) has taken a small but significant place in American culture. Walter Sullivan, Frank Drake, and David Grinspoon, among many others, have written popular accounts of the science. Motion pictures such as Contact (1997) and Species (1995) have visualized the field with the tools available to filmmakers. The SETI Institute’s radio program Are We Alone, hosted by astronomer Seth Shostak, makes the science a part of the heavily mediated environment of popular entertainment. There is also the small, robust field of historical and critical scholarship. It is in fiction, however, that SETI has found its most effective expression for general audiences. This medium provides literary arguments for why the science matters in contemporary life. I argue that it is fiction about SETI that helps us model the societal implications of extraterrestrial contact.

Fiction writers such as James Gunn and writer-scientists such as Carl Sagan have produced a literary subgenre that I call the CETI (communication with extraterrestrial intelligence) novel.¹ These writers take the science seriously and share an interest in

² For the purpose of distinguishing it from the science (SETI), I use for the fiction the original acronym for the project: CETI or communication with extraterrestrial intelligence. John Billingham recalls that the change in nomenclature was inspired by the establishment of the science as a NASA project in the early 1970s. David W. Swift, SETI Pioneers: Scientists Talk about Their Search for Extraterrestrial Intelligence (Tucson, AZ: University of Arizona Press, 1990), pp. 258–259.
both representing the project and its possible social and political effects. They are also committed to dramatizing the early, founding goal of SETI—communication with extraterrestrial civilizations. This leads them to consider ideas that are always revisited in debate around the project. Could we communicate with an intelligent species that is not human? What effect would such an exchange have on us?

These questions create challenges of both form and content for the CETI novelist. How might these issues and the debates they inspire be presented to general readers, engaging the emotions as well as the intellect? One solution is the genre’s focus on the future that a SETI contact could produce; the CETI novel always takes place in a recognizable present and that future is always just around the corner. It is the closeness of that fictional present to our world that makes CETI narratives credible, and it is a futurism that helps the writer emphasize the science’s connection to contemporary life. It is through this link that the CETI novelist hopes to sustain the reader’s interest in SETI as necessary to any future we might create.

The central premise of a CETI narrative is that the search for an artificial signal from another world is successful. What follows is a fruitful exchange of scientific and cultural ideas. Whatever arguments are used to sustain this presumption, it is liberal hope that inspires this hypothesis. Discovering the knowledge we need to make manageable the social and political problems of our world is the foundation of that hope. It forecasts a terrestrial future in which humanity survives its internal divisions and its Malthusian consumption of Earth’s resources. In other words, communication with extraterrestrial others would prompt us to communicate with each other. We could then work together to make the world more livable and sustainable. Thus, human civilization would break out of the historical bind in which it finds itself.

Steven Dick argues that “perhaps the classic expression” of SETI in fiction is James Gunn’s 1972 novel, The Listeners. This book is my test case for the futurist concerns I have outlined—my model for the CETI novel as a distinct literary genre. Although other works in fiction and nonfiction preceded it, Gunn’s achievement is to create a narrative that speaks to prevailing social concerns while introducing the reader to this new science. Here SETI is not merely a convenient backdrop for the agony of middle-class lives; it is the raison d’être of those lives. This emotional as well as intellectual centrality helps clarify the feeling of social mission the writer finds in the science.

3. Writers such as Don DeLillo and Stanislaw Lem have been interested in the science. However, they engage it both as a demonstration of the limits of science and of our ability to communicate through language. This is very different from the ideology and spirit encoded in the CETI novel as a narrative form of scientific representation. Don DeLillo, Ratner’s Star (New York: Vintage Books, 1989 [1976]) and Stanislaw Lem, His Master’s Voice (Evanston, IL: Northwestern University Press, 1999 [1983]).

In the following paragraphs I will explore Gunn’s solution to the problem of introducing a new science to nonspecialist audiences. As I present it here, Gunn follows two distinct but conjoined strategies: he creates a form that provides the historical and philosophical background against which to view SETI, and he tells a story in which difficult social debates are resolved by lessons learned from science. The novelist’s goal is to strike a balance between the didactic demands of his subject and familiar fictional conventions. Thus, I argue, Gunn makes a fiction in which SETI is part of our ordinary culture—the herald of an extraordinary future.

ON FORM

Gunn’s *The Listeners* may be viewed as an experimental novel within the context of genre practice during its composition. It was written serially, as a series of short stories for *Galaxy Magazine* and *The Magazine of Fantasy and Science Fiction*, from 1968 to 1972. Marketed and published as general fiction, not science fiction, in 1972, the novel has been considered a “fix-up,” defined by Clute and Nicholls as “a book composed of previously written stories which have been cemented together.” The cement, in this case, is what Gunn calls “computer runs,” interchapters that provide a historical and philosophical overview of SETI and the future posited by the novel. The usual practice with fix-ups, such as Ray Bradbury’s 1951 collection *The Illustrated Man*, is to provide fictive interchapters linking together stories that otherwise have no compositional relation to one another. Gunn’s strategy is more like that used by John Steinbeck in his 1939 novel *The Grapes of Wrath*; it offers the reader a social and political context within which to understand the narrative portions of the work.

*The Listeners* presents SETI as a humanistic science, a research agenda that boldly addresses our social and philosophical concerns through the question of whether sentient life exists elsewhere. Gunn’s formal strategy is to create a narrative in which science-based exposition and debate are entangled with conflicts around the politics of race, between religion and science, between a middle-class status quo and a utopian future, and around the private misunderstandings of husbands and wives, fathers and sons. In this narrative context, Gunn’s computer runs present three lines of argument: history and futurist speculation, inspirational epigraphs from literature, and statements from SETI pioneers. These arguments create a dialectic that defines the science as a movement that can change the course of individual and collective lives.

Through historical reconstruction and speculation, Gunn gives us a select history of science. We learn that SETI was born when Cocconi and Morrison discussed the feasibility of sending interstellar messages during work on “gamma

---

ray production from the Crab Nebula.” The Big Bang and inflationary universe theories are presented, in free verse. The course of future progress in cryonics, genetics, psychiatry, and weather control is indicated. Advances in technology such as a milk-making machine (heralded as a part of recycling waste and not as a way to eliminate hunger), computer-generated art, and the first Mars landing are cited. We are given snippets foretelling the future of media technology from holovision to the responsive environment (“respen”) to a full-spectrum sensorium (“V-A-F-S”), a scenario that anticipates the computer-based concept of virtual reality. Lists of stars, galaxies, and great astronomers round out Gunn’s sketch of knowledge acquisition and engineering prowess. The novel’s Listening Project is presented as a significant development in this hymn of science and invention.

In mid-twentieth-century America, a common concern was that social and political progress did not keep pace with advances in science and technology. Gunn’s computer runs offer a future in which society and politics keep pace with technoscience. Wealth is more equitably distributed, Arabs and Israelis work together, the prison–industrial complex fades into irrelevance, the 4-day week and 13-week vacations become standard, and an increase of leisure means that the amateur is reconstituted as a respected and productive social position. Gunn anchors this speculation in a bulletin on the growth of national and global wealth:

The [United States Bureau of Economics] attributes the solution of many of the problems that troubled the world a half century ago to the dramatic growth in the Gross World Product through automation, fusion power, greater use of computers and cybernation, and new educational methods.

Here the link between social and technological progress is completed by economic development. Technoscientific progress sponsors wealth creation, which in turn empowers and sustains the resolution of social and political problems. Given current conditions, this scenario may be optimistic, but is powerful nonetheless because of both the utopian desire it encodes and its resonance with familiar hopes in a culture resistant to socialist alternatives. It is the accumulation of wealth under an efficient, global capitalism guided by a social democratic liberalism that empowers and sustains Gunn’s vision of social and technological progress.

---

8. Ibid., p. 141.
9. David Potter’s landmark study, People of Plenty, states this position in a more formal context. Potter argues that a “culture of abundance” is the thing that explains American character and gives the nation’s people a unique place in history. The United States will survive if it can avoid the pitfalls of scarcity. David M. Potter, People of Plenty: Economic Abundance and the American Character (Chicago: University of Chicago Press, 1958).
The bottom line here is that the world is reformed, socially and politically. However, it is important to note that Gunn's future describes liberal reform within political and economic institutions that do not change. In the near term, the world does not become unrecognizable from a mid-twentieth-century capitalist perspective, as it does in Kim Stanley Robinson's post-Marxist Mars Trilogy. The hope is that the United States of the twentieth century will inherit any extraterrestrial knowledge, surviving its own problems and serving as a model for the rest of the world.

In Gunn's interchapters the mixture of history with futurist speculation deploys a historiographic vocabulary familiar in science fiction. By the mid-1960s the gesture is arguably a cliché. Gunn's desire to teach, however, leads him to directly include the results of his research into the early history of SETI. The computer runs are also an archive of the scientific commentary that inspires the narrative. It is here that we are introduced to first generation of C/SETI thought. Extracts from the seminal paper by Giuseppe Cocconi and Philip Morrison, Cocconi's letter to Bernard Lovell, estimates of the likelihood of living planets and intelligent species by Sebastian Von Hoerner, and Carl Sagan's, Frank Drake's, and Ronald Bracewell's early statements on the kinds of searches possible and the time scales involved are imbricated with fictive explication and history. Gunn combines scientific propositions with belletristic rumination from speculative essays by Eiseley, Shapley, and Dyson. Here we have scientists functioning as writers—intellectuals who can speak authoritatively about why thinking about sentient extraterrestrials is important to our sense of self and destiny. Their words are carefully dated, allowing us to locate utterances from the late 1950s through the 1960s. Gunn's strategy here is to support and authorize his future history with direct reference to the thought of those scientists responsible for both creating SETI and promoting the science in print for nonspecialist audiences.

What Gunn has made is a model for integrating fiction and science writing. Coupled with the emotional resonances produced in the novel's fictional chapters, science (particularly new science) is made compelling or, at least, interesting for general audiences. The goal here is to gain cultural credibility for SETI, building a case that makes it look like more than science fiction. In the computer runs, it is Gunn's references to literature that supply the cultural capital necessary for

---

12. For science, especially science that wrestles with pre-existing cultural tropes such as the idea of extraterrestrial life, science fiction is a problem as well as an invaluable resource. Sensitivity about the standing of science in relation to science fiction is indicated by Giuseppe Cocconi's reluctant admission to Bernard Lovell that the notion of life and intelligence on other planets might, "at first sight [look] like science fiction." He goes on to argue that it is not (Gunn, p. 28).
that credibility. British and American authors Walt Whitman, Alice Meynell, Gerard Manley Hopkins, and Edward Lear link the reader to the thread of fanciful or religious speculation that has always been a part of Western (English-language) literature. Within this tradition Gunn also takes care to include H. G. Wells, Murray Leinster, A. E. van Vogt, and Theodore Sturgeon—authors who have helped formulate the modern conception of extraterrestrial sentients and have had powerful influence on how to present narratives of human–alien contact.

For analytical purposes I have split apart these literary (and nonfictional) threads. Gunn’s strategy, however, is to weave them together. He juxtaposes religious texts (the Judeo-Christian Bible, the Hindu Rig Veda) with modern literature with history of science with science writing, speculative essays, futurist scenarios, and government reports. Differences and historical context are indicated by changes in typography and dated attribution. The effect is a cultural babble that mirrors the cacophony of radio voices depicted in his fiction. In this orchestration no particular utterance is given prestige or priority above another; each saying builds on and offers support to the next. As Gunn’s science heroes must decode the Message sent by the Capellans, so the reader is to decipher the cultural puzzle of the interchapters.

The book’s final chapter, “The Computer,” integrates fiction, nonfiction, and literary and science history. Having taught us how to read C/SETI as science and culture in the previous chapters and computer runs, Gunn hopes that we are ready to interpret the Message of the novel and to integrate it into our own sense of how the world does and will work. The effect of his stylistic formula is to indicate that there is more at stake here than either disinterested curiosity or personal salvation. Nothing less than the future of the human race is at issue. However melodramatic this might sound, Gunn’s effort provides insight into the mid-twentieth-century anxieties and hopes that informed the creation and reception of SETI science.

On CETI and Race

During the composition of The Listeners in the late 1960s and early 1970s, a great deal of criticism was leveled at the U.S. space program, for example, cultural critic Lewis Mumford’s contemporaneous judgment that spaceflight dreams are “infantile fantasies.” But as I have noted elsewhere, “[T]he political voice that served as the iconic focus of liberal/left dissent from the space vision and its economics came from the nation’s black community.” The Southern Christian Leadership Conference, for example, organized a protest march during the Apollo 11 launch (on 16 July 1969) that questioned the expense and the societal importance of the

venture. Astrofuturists, such as science fiction writer Ben Bova, felt it necessary to directly confront African American criticism, offering the exploration of space as a solution to the racial conflicts of the time. Gerard O’Neill notes in his 1978 book, *The High Frontier*, that the ability of science to address contemporary social problems was also in question on university campuses. Working as a public relations officer at the University of Kansas at that time, James Gunn was well aware of the problem. Indeed, in his preface to the 2004 edition of the novel he tells us that it was his job “to explain student unrest to the various University publics.”

It is in *The Listeners* that Gunn makes his most compelling contribution to that social and political debate. In the chapter “Andrew White,” the author offers a description of how the discovery of an extraterrestrial civilization might affect the United States. However, how race is seen (as a social and political problem) must be resolved before the future that follows unfolds. In this novel the foundation of political hope is SETI’s potential for changing or eliminating race’s historical standing as an ineradicable mark of human difference.

Gunn draws our attention to race by filtering the reader’s view of C/SETI through the thoughts of Andrew White, the African American president of Gunn’s near-future United States. This is a critical and perhaps bold move inspired by the racial tensions of the 1960s and early 1970s. Here Gunn conducts a literary thought experiment that highlights problems while setting the stage for the solution. The hope that social and political advance will move in company with progress in science is fundamental here. Political progress is signaled by the deliberations of an African American occupant of the Oval Office; scientific progress is represented by the Listening Project’s success in discovering an extraterrestrial message. Gunn creates this character not to examine political racism in high office (as Irving Wallace did in his near-contemporary novel, *The Man* [1964]), but to raise at least three pertinent questions: What would it mean to speak for humanity to an extraterrestrial civilization? Who could authorize such a communication and to what end? And, is civilized communication truly possible between different races, cultures, civilizations

---

18. Gunn, p. xvii.
What binds these issues together in *The Listeners* is the kind of social future we hope for and how the past informs it.

Gunn’s President White must decide whether the novel’s CETI project may share news that a message has arrived from a planet orbiting the double star Capella and send a reply. This issue is complicated by an argument with his son over the meaning and relevance of race now and in the future. What is at stake is whether the president can accept the Capellan Message as a furtherance of the political evolution that he represents.

As he sets up White’s view of C/SETI, Gunn is careful to establish the president’s authority as holder of the nation’s highest office. We first see White in the Oval Office and our attention is drawn to its size:

> The office was big . . . . Across the broad blue, deep-piled carpet with the woven seal in the middle to the carved white door by which visitors entered was a good twenty yards—that was bigger than the entire flat in which he had been born . . . . ²⁰

This scene setting makes the Oval Office Andrew White’s natural environment, a move underscored by the reference to humble beginnings. White’s log cabin story has him escaping from urban poverty, but otherwise cleaves to this familiar aspect of American political hope: that the small, the weak, and the disenfranchised can achieve greatness in this country. And, as befits a storybook president who is entrusted with national destiny, Gunn makes his chief executive larger than life:

> He stretched his shoulders and felt the long, flat muscles rippling under the layer of fat too many chicken dinners had put there, and he knew he was a big man, an imposing president, six-feet-six from the soles of his feet to the top of his close-cropped hair, and the physical equal of any of them, of anyone who came through that door. ²¹

Gunn’s goal here is to write a president whose authority we do not question. His race is important to the narrative but is not represented as a problem that undermines his effectiveness or longevity in office.

President White’s race also signals that he represents a future in which social change is possible. The writer’s strategy of linking his decision-making to an

---

19. Andrew White, Gunn’s African American president, is not a unique fictional invention; several other popular writers responded to the “race problem” of the 1960s by mounting fictional speculations on a black presidency. Irving Wallace’s early 1960s best seller, *The Man*, predates Gunn’s story by several years. A film based on book, starring James Earl Jones as the first African American president, was released in 1972. Gunn’s short story, “Andrew White,” was published that year in the January-February issue of *Galaxy Magazine*. Gunn has stated, however, that he has not read the Wallace book. He is, however, familiar with the movie (private conversation with author, 7 July 2007). The connection, therefore, has more to do with contemporary social thinking rather than a specific influence.

21. Ibid.
historical and iconic president, Theodore Roosevelt, underscores this. Gunn has White remember Roosevelt’s reputation for making up “his mind somewhere in the region of his hips.” Whatever we remember about Roosevelt’s racial beliefs connecting White to this popular historical figure, and by association to the relatives who followed him as president and first lady, indicates how we are to view White as an author of progressive social reform. In this narrative he is authorized as a man, as a father, as president, and as the representative of an historically aggrieved population who can open the way for a radical change in human relations.

The dynamic interchange Gunn stages between SETI and the personal and political investments of his cast allow him to demonstrate how science might solve race as a social problem. For Andrew White, who was “wound up in the ghetto” and who used the White House to “right the ancient wrongs,” race and racism are fundamental aspects of human character. As a career politician, he understands “that there were differences between men and these differences inevitably affected how they felt about each other, about themselves.” These differences, coupled with the human capacity for, as the president argues elsewhere, “malice and greed . . . the persistent search for advantage” make him pessimistic about the state of the future he is helping to create.

On the other hand, the president’s son, John White, is convinced that the past his father remembers “is irrelevant” to the world in which he lives. If his father argues that the battle for civil rights is not finished, John believes that it is. Impatient with his father’s account of past troubles, John argues that “[B]eing human is being able to do something different.” It is at this point that Gunn has his fictional president reflect, “The boy was an alien, but somehow he had to communicate.”

Here Gunn emphasizes the metaphorical link between speculation about extraterrestrials and the “aliens” we live with here on Earth. That connection illuminates SETI’s potential for changing how we see contemporary social problems. In The Listeners, resolving this generational conflict over race is a matter for science, not politics.

In this novel there is no question that discovery of an extraterrestrial civilization will have tremendous impact on our world. Considering the prospect, President White comes to the conclusion that it is “bad news.” He tells Robert MacDonald, the humanist and engineer who directs the Listening Project, that an alien message could sow “the dragon’s teeth of dissension and strife which may well destroy this country.” His concern is that public knowledge of the Capellan Message would disrupt the domestic tranquility necessary for reform: “We have solved many of the problems that threatened to tear this nation apart at the time the Project was started and trouble will keep us from solving the others. We need, calm, serenity . . . ,” not

22. Ibid., p. 104.
24. Gunn, pp. 110, 114, 126.
25. Ibid., pp. 105, 110.
change that is “unmanageable.” Director MacDonald’s answer to these concerns is that the act of communication, particularly scientific and cultural communication, is our guarantee that social progress would be fostered and not hindered should SETI achieve its aims. Gunn has his scientific humanist visionary list at least three arguments in favor of this position: (1) if the president allows scientists to release the Message and their interpretation of it, then public understanding will follow; (2) communication is a civilized act that precludes violent intent by sender or receiver; and (3) once the public learns the facts, it will realize that the benefits of communication outweigh the risks. These arguments outline a science-based hope. It is a brief that embraces the changes that would follow the discovery of an advanced extraterrestrial civilization.

The Listeners is a book written in praise of science as an activity that fosters communication between people who differ by reason of border or birth. SETI is presented as an inquiry that ennobles the human species and guarantees its future. This is a minority opinion in a popular culture in which thrilling horror-from-the-stars stories function as an entertaining commonsense. Species (1995), for example, is a film that directly mocks SETI (with what purports to be footage of astronomers sending the 1974 Arecibo message) as the folly of naïve scientists. The message received by the film’s protagonists produces a dangerous white-black-Asian hybrid, a monstrous miscegenation that preys on “normal” humans. Communication with an extraterrestrial civilization is dangerous and sets up an interspecies conflict (rendered in visual terms as traditionally racial) that could lead to the extinction of terrestrial intelligence. This is “the boogeyman from the stars” cliché at which Gunn’s project director casts an indulgent smile. If popular narratives insist that communication between different races is impossible, then narratives inspired by science (SETI science, at least) argues that communication is possible and necessary for our survival. In American cultural discourse this position allows SETI to stand out as a science that seeks new discoveries; it does so in part because it runs counter to popular narratives around race and the fears they express.

This takes us to the hope that Gunn engages through the thematics of race and communication: the progress of human civilization and its long-term survival. If human beings can talk to one another, we may also engage in conversations with beings from other worlds; if human civilization can mature, it could join what Ronald Bracewell calls the “galactic club.” If we accept these propositions, then we find ourselves considering a “universal” future—an era in which we create an ethical reality that transcends what Edward Said calls “the easy certainties provided us

27. Ibid., pp. 124, 125.
28. Ibid., p. 125.
by our background, language, nationality, which so often shield us from the reality of others.”30 Thus, the narrative resolution of conflict between races and generations in The Listeners provides a social and political justification for SETI: that through this science we may discover the material grounds for a universal language, an episteme that does not assume incommunicability of experience across differences of culture and biology.

Gunn underscores this goal by having his president perceive a truth and give up his son. The truth comes to him graphically in the reply that MacDonald would like to send to the Capellans. It is a simple pictogram of dots and spaces, a message that contains some basic biological and astronomical information. President White laughs when he sees it:

![Figure 28.1—Listening Project Message (James Gunn, The Listeners [1972]).](image)

“I’m sorry . . . I wasn’t laughing at the answer. I don’t begin to understand half of what’s here. But that’s obviously a father and a mother and a son—a child—and the Capellans would have no way of knowing whether they were white or black.”31

If the president’s fear is that any dialogue with the Capellans will only serve to exacerbate our parochialism, then MacDonald’s answer seems to set that aside. At this level of communication, human differences are trumped by the reproductive biology that sustains us. The biological insight that humanity is a single species shapes White’s decision to let the project go forward. From this point, the history foretold by The Listeners takes a hopeful turn.

Because Andrew White is an African American president, his decision is doubly authoritative in answering 1960s questions about science’s relevance to social problems. What is at stake here is not only the acceptance of SETI by a politically active and critical African American community, but also whether the project is open to participation by its members. Gunn answers this last question by having John White, the president’s son, become a contributing member of the Listening Project. After John makes an important breakthrough toward deciphering the Capellan Message, the president allows him to join the project. John eventually succeeds MacDonald as Listening Project director.32

In the spare, economical world of Gunn’s fiction, the symbolic import of this is obvious. It underscores the message that C/SETI is (or should be) the work of a scientific community that represents all of humanity. It is through this openness that Gunn makes his most direct plea for science as a social as well as an intellectual good. Gunn has MacDonald state, “The fraternity of science is closer than the fraternity of birthplace or of language.”33 By becoming part of this fraternity, John White represents the hope for the future that Gunn sees in the search for extraterrestrial intelligence.

It is possible to dismiss the position that Gunn articulates, in championing SETI as “nothing more . . . than salvation from the stars,” following George Basalla’s critique in Civilized Life in the Universe (2006).34 What Basalla fears, perhaps, is that SETI, as an ongoing public discourse, amounts to a ceding of scientific and political ground to unreasoning popular culture. The literary experiment that Gunn conducts, however, allows us to mount a more subtle analysis. The novel’s hopes for social and political progress notwithstanding, good news from the stars is not a panacea, a deus ex machina that resolves all the difficulties we face. Having received the Capellan Message, humanity is given neither final answers nor a perfect social order, but simple confirmation of a way forward. History continues, in a different register, with plenty for the human race to learn and accomplish:

The Project set up nearly one hundred fifty years before to listen for messages from the stars and the Message from Capella that it had received and deciphered had given Earth and its people ninety years of peace in which to explore the other aspects of humanity besides aggression. The problems that had seemed so difficult, virtually unsolvable, one hundred and fifty, even ninety, years before had seemed to solve themselves once the world relaxed.35

33. Ibid., p. 130.
35. Gunn, pp. 177–178
The lesson drawn here presents two effects of the Capellan Message: it helps humanity take stock, improving its situation; and the answer to our reply will help spark a change, the “something different” for which John White argues.36

The final chapter of the book, “The Computer,” clarifies what is new about this emerging difference. Throughout the novel, the Listening Project computer is used by astronomers as an instrument and archive. Macdonald tells White that “[V]irtually the entire written history and literature of mankind— in all his written languages— is stored in there.” It is a “research tool” that contains the sum of human cultural achievement in art and science: the universal knowledge necessary for a universal future. The machine represents the human race in the project of decoding any message we might receive. In the novel’s closing lines we are told that when a call from a second extraterrestrial civilization arrives, the computer is “at least half Capellan.”37 In other hands, this would be prelude to xenophobic machine-breaking.38 In the context of Gunn’s narrative, however, it represents change for the better. Gunn has Macdonald’s grandson, William, make the point:

We have received a legacy more valuable than the physical possession of another world, with all its natural treasures, and the world’s scientists and scholars and everyone else who wishes to explore it may spend their lifetimes studying it, interpreting it, and adding bits and pieces of it to our civilization, enriching us by a whole new world and everything it has.39

We are presented with a new dispensation, one in which the impact of a wiser, more advanced extraterrestrial culture produces radical change here on Earth.

Thus, The Listeners is a novel that fuels our expectation that, given the right pressure, the human species can change for the better. Gunn’s universal computer heralds the postbiological universe that Steven Dick has theorized elsewhere.40 Hope resides in the cultural and political evolution fostered by our technology. However,

36. Ibid., pp. 110.
37. Ibid., pp. 120, 192.
38. Indeed, Hoyle teases us with this possibility in an early novel, using SETI as a jumping-off point for a narrative of uncertainty about extraterrestrial motives. Fred Hoyle and John Elliott, A is for Andromeda (New York: Harper, 1962).
discussion of artificial intelligence, Bracewell probes, and the like is beyond the brief of this narrative. More important is Gunn’s presentation of a technoscientific trajectory in which the politics of race are rendered irrelevant, leading to a species-wide transformation that fulfills the promise of scientific humanist values.

The amelioration of race is prologue to the reconfiguration of women’s roles as the new (post)human reality emerges. Heretofore, women are supernumerary to the creation of the future. Their principal function is to secure the succession of great men and their ideas. However, prior to the arrival of the Capellans’ final message, William MacDonald tells a waiting world that while he has “no son . . . I do have a daughter who is now a member of the Project staff.”41 Thus, the father-son succession that sustains the project directorship in the novel’s history is broken. The future created by the novel’s C/SETI project lays the groundwork for both racial and gender equality. On the eve of the women’s movement, Gunn imagines that the institutions of science represented by SETI are the vanguard of progressive social and political change.

Whatever we make of these positions, it is important to note the power of the technoscientific speculation that authorizes them. Here scientific and technological invention are the vanguard of social and political change. This sentiment is driven by the hope that progressive, evolutionary trends in science and technology, history, and society will allow our civilization to transcend human frailty, poor judgment, and bad luck.

Gunn’s contribution is to connect formal invention and his reading of race with the scientific and social debates current during SETI’s first decade. Thus, The Listeners has the complexity and depth it needs to serve as a dress rehearsal for how America might react to the news that “we are not alone.” With its interchapters containing quotations from SETI’s pioneering generation, The Listeners is also a model for how the traffic between science, society, and literature moves at particular times in our history. This presentation of SETI’s social mission makes the science credible within the social investments important to a general reading public. It also, as SETI League executive director Paul Shuch says in his introduction to the 2004 edition, “inspired a generation of SETI scientists to pursue the seemingly impossible.”42 It is the desire for a future occupied by intellects other than our own that gives C/SETI narratives the intellectual, formal cohesion necessary to argue for the social relevance of its authorizing science. As presented here, this branch of astronomy is neither apolitical nor disinterested in the nature and course of human life. Its practitioners hope that by searching for and gaining more knowledge about the standing of life and intelligence in the cosmos, old-fashioned values such as tolerance, equity, peace, and freedom will be the anchoring virtues of any global destiny. It is a code of moral and intellectual conduct as well as a disciplined way of fixing our celestial knowledge.43

41. Gunn, p. 183.
42. Ibid., p. xi.
At the end of the novel, humanity stands in relation to an extraterrestrial civilization in the way that the Renaissance was influenced by classical antiquity: intellectual and cultural beneficiaries of a long-dead civilization. What is achieved is not utopia but, perhaps, a better world. *The Listeners* certainly argues for this possibility. It has produced or reinforced a pattern of expectation that would lead some to embrace rather than fear communication with another intelligent species.
The idea of progress is clearly central to American national identity, yet the popularity and credibility of the idea have undergone significant fluctuations over the course of American history. This essay assesses how the onset of space travel stimulated an attempted revitalization of ideas about progress that, by the late 1960s, were coming under increased attack. The idea of progress has typically advanced three claims: (1) there are no fundamental limits on the human capacity to grow, however growth is defined; (2) advancements in science and technology foster improvements in the moral and political character of humanity; and (3) there is an innate directionality in human society, rooted in societal, psychological, or biological mechanisms, that drives civilization toward advancement. American believers in progress quickly embraced space travel, viewing it as a vindication of the doctrine’s original claims about the near-inevitability of human improvement. With space travel understood in this fashion, the fate of the space program took on a far greater meaning than developments in other areas of technological endeavor, as it became symbolic of the entire directionality of human civilization. The early and astonishing success of Apollo, followed almost immediately by signs of disarray, served to stimulate a new vision of progress and then quickly threaten it. In this context, a space advocacy literature arose that was simultaneously grandiose about the human future yet intensely fearful about missed opportunities. This confluence of ambition and anxiety continues to characterize both the pro-space movement and the larger debate about the American future in space. As the historian Charles Beard noted: “Into the mood of the American people . . . the idea of progress fit with extraordinary precision . . . . It remains, and will remain, a fundamental tenet of American society, and while vigor is left in the race it will operate with all the force of a dynamic idea rooted in purpose, will, and opportunity.”

Americans have been more deeply wedded to the idea of progress than perhaps any people on the face of Earth. The key claim of the idea of progress—that human civilization has moved and will continue to move in a desirable direction—has been central to American culture and identity for virtually all of the nation’s history. Indeed, many would argue that a profound faith in progress has been one of the key features distinguishing Americans from people elsewhere, and a recurring source of the country’s distinctive appeal across the globe. What happens, then, when the idea of progress starts to lose credibility? How do Americans react when they become fearful that the direction of society has become negative rather than positive? The period of the late 1960s and early 1970s provides an example of a time when the American faith in progress started to unravel. Although belief in progress has arguably recovered partially, most observers would still view the late 1960s as a turning point after which the idea came under siege in ways that had not been experienced previously.

The argument of this essay is that the rise of new forms and doctrines of space advocacy reflects exactly this crisis in the idea of progress. If the forward march of humanity (with America noticeably in the lead) had been halted, something had to be done. A movement into space was proposed as the solution. Thus was born the modern pro-space movement, and the contemporary fusion of the idea of progress with ideas about space travel, space development, and, most of all, space colonization.

Over the last 40 years, space advocates have constructed a set of doctrines that address all the key components found in the idea of progress since it first took modern form during the Enlightenment. This new pro-space ideology was a reaction to the problems that had become apparent by the time of the first Moon landing, namely, environmental crises, limits to economic growth, and fears of cultural decay. Space advocates proposed solutions to these problems and others. They concluded that an expanded space program was the essential condition to revive both the idea and reality of progress. The irony was that they embraced this belief at the very moment that the Apollo program was coming to a close, and the future of NASA and space travel becoming increasingly uncertain. Thus, a strong edge of anxiety and urgency was introduced into the writings of space advocates. The means to ensure progress had been found but would soon be lost forever if government policy was not properly adjusted. This combination of certainty about the path toward redemption alongside anxiety about the possibility of missing a singular opportunity energized the new pro-space literature and encouraged the growth of an accompanying space advocacy movement.

The Idea of Progress

Despite the many controversies over whether progress is actually taking place, there is little dispute about how to define the idea itself. J. B. Bury’s classic formulation of 1920, with its succinct assertion that the idea “means that civilization has moved, is moving, and will move in a desirable direction,” remains as useful as any proposed since. But theories of progress have always tried to do far more than simply attach a normative gloss to the passage of time. By necessity, they have embraced a set of larger claims, captured in the following mutually reinforcing and interlocking premises:

1. **No Limits.** There are no fundamental limits—nor should there be—on the collective human capacity to grow, no matter how growth is defined (which may be in terms of knowledge, wealth, power, population, or morality). Progress is endless (or at least indefinite for all practical purposes).

2. **All Good Things Go Together.** Advancements in science and technology, and the resulting mastery over nature, expand our knowledge, wealth, and power. In so doing, they bring improvements in the moral, political, and spiritual character of the human race. The elements of progress are linked to one another and are mutually reinforcing.

3. **Innate Directionality.** There exist developmental tendencies, rooted in societal, psychological, or biological mechanisms, that make it far more likely that human civilization will move “upward” toward greater control and understanding of nature and ourselves, rather than “downward” toward chaos and entropy. Progress is, if not inevitable, always highly probable.

Whether one was a liberal who embraced science, markets, and technology; a Marxist who saw class conflict at work in capitalist society; or an evolutionist who focused on the winnowing effects of natural selection, these three premises were always addressed, either directly or implicitly, in the great nineteenth-century theories of progress.

Unfortunately for defenders of progress, all three of these premises became less convincing during the course of the twentieth century. Major limits on economic, demographic, and even intellectual growth were identified, and their importance was

---

widely proclaimed in both elite and popular culture. A belief that there are innate human tendencies toward progress was undermined by the evidence that humans were inherently violent or even self-destructive due to deep-rooted psychological or biological drives. Science and technology, it was suggested, have advanced far out of proportion to the capacity of humans to control them rationally, making total self-destruction as likely as benign development. Advancements in humanity’s control over nature were thus no longer necessarily viewed as automatic *improvements*, and could even be seen as detrimental, contributing to the further estrangement of humanity from its natural environment. For many, gains in science, economics, and technology seemed to have corrupted humanity, producing a culture of widespread pornography, greed, and violence, and a political sphere dominated by the trivialized discourse of mass marketing. Summarizing a vast literature, physicist and historian Gerald Colton concluded in 1980: “Future historians will probably record that from the mid-twentieth century on, it was difficult for anyone to retain faith in the idea of inevitable and continuing progress. People increasingly use the word in quotation marks or with mocking sarcasm or speak not of progress in civilization but in barbarism.”

**Enter the Space Advocates**

It is in this context that the space advocates enter the debate, with their own agenda to revitalize the idea of progress and, in so doing, to buttress a central component of American national identity. Although space advocacy ideologies and organizations have existed in various forms since the first decades of the twentieth century, the 1970s saw the formation of a pro-space movement that was determined to build upon the successes of Apollo by creating the setting for an imminent migration into space on a massive scale. The most notable of these new advocates was Princeton physicist Gerard K. O’Neill, who foresaw the creation of an expanding human civilization in space by the early 1990s. At the core of his vision was the establishment of gigantic rotating colonies, shaped liked a sphere or cylinder, in which tens of thousands of inhabitants living on the interior surface would experience the sensation of gravity produced by centrifugal force. With sunlight beamed in by massive mirrors, these colonies could provide park-like conditions for their inhabitants and a lifestyle that resembled that of a comfortable American suburb. The economic rationale for this massive endeavor would come from the construction of enormous grids for collecting solar energy, which would then be converted into microwaves and beamed down to receptors on Earth. In this manner, O’Neill anticipated that the movement into space could provide clean, limitless, and inexpensive power for a world that was facing worsening shortages of energy and raw materials. The Space Shuttle, which promised to soon provide low-cost access to space, would be one of several vehicles that would

ferry construction crews to space, eventually arriving at Lagrange point 5 (L-5), the location where the balancing of the gravity of Earth and the Moon would allow a colony to remain stationary.

This bold vision of a profitable and practical future in space prompted the formation of an interest group called the L-5 Society, which was set up in 1975 in order to promote the creation of O’Neill-style colonies as soon as possible. The group embraced the slogan “L-5 in 1995” and proclaimed that its goal was “to disband the Society in a mass meeting at L-5.” Within a few years, the organization had attracted considerable attention, and the O’Neill vision of a new human future in space was the object of serious study in Congress and NASA. By the mid-1980s, however, the limited success of the Space Shuttle, as well as the subsidence of energy prices and the avoidance of other predicted catastrophes, encouraged the postponement of the space colonization dream to a rather more distant future. By 1987, a demoralized L-5 Society had merged with the National Space Institute, a more subdued pro-space group established in 1974 with closer ties to NASA, and together formed the National Space Society (NSS), which continues as an active pro-space group to the present day. The NSS has eschewed the vision of L-5 colonies as the only desirable means to populate space, and toned down the messianic rhetoric that made the L-5 Society somewhat notorious, but it remains committed to the goal of “people living and working in thriving communities beyond the Earth.”

While NSS and its supporters delayed their dreams, a second group of space advocates emerged in the 1990s with much of the same élan that had characterized the pro-space partisans of the 1970s. For these activists, the plan was to colonize Mars rather than to create artificial spheres in space. As such, their program was simpler: they advocated immediate steps to begin the settlement of the Red Planet, hoping to send the first humans in the early decades of the twenty-first century. Supporters of Mars colonization believe that the long-term project of developing a human civilization on Mars will promote social cohesion and economic growth on Earth, and create a new branch of civilization that will rival in its accomplishments anything that mankind has done previously. The most enthusiastic proponent of this plan has been the engineer and author Robert Zubrin, who wrote the 1996 book *The Case for Mars* and was instrumental in the founding of the Mars Society, an organization dedicated to making Mars settlement the main goal of America’s space policy.

A third contemporary pro-space group is the Planetary Society, founded by scientists Carl Sagan, Bruce Murray, and Louis Friedman in 1980 to encourage “the exploration of the solar system and the search for extraterrestrial life.” With more than 100,000 members from numerous countries, it is the largest single pro-space interest group, but has largely promoted exploration as a value in its own right, showing little

---

interest in the grandiose vision of space industrialization and colonization endorsed by NSS and the Mars Society. Nonetheless, the society has strongly supported the value of a human mission to Mars and has worked closely with other space groups to support President George W. Bush’s Vision for Space Exploration initiative. And Sagan himself became a prominent advocate of the larger goal of space colonization in his writings of the 1990s, providing influential and eloquent support for a continued human role in spaceflight and the long-term goal of space migration.

**Space Development and the Idea of Progress**

Although the various pro-space intellectuals and space advocacy groups often endorse different practical programs and strategies, they use similar arguments in justifying their vision of the human future in space. As they have attempted to persuade a skeptical public of the desirability of their (rather expensive) programs, they have come to address all three of the classical premises of the idea of progress.

**No Limits**

The modern view of progress is resolutely opposed to the idea of limits, including limits in space and time on the growth of the human species. It is perfectly logical, therefore, that many authors see the rise in recent decades of the idea of “limits to growth” as signaling the decisive end of the idea (and reality) of progress in our time. “The belated discovery that the Earth’s ecology will no longer sustain an indefinite expansion of productive forces deals the final blow to the belief in progress,” Christopher Lasch confidently asserts.7

Space advocates will have none of this. Responding to the first appearance of the “limits to growth” idea, pro-space intellectuals of the 1970s were eager to assert that space could be the source of limitless new reserves of energy and natural resources. In promoting his scheme of magnificent L-5 colonies, Gerard K. O’Neill wrote:

> The human race stands now on the threshold of a new frontier, whose richness surpasses a thousand-fold that of the new western world of five hundred years ago. That frontier can be exploited for all of humanity, and its ultimate extent is a land area many thousands of times that of the entire Earth. As little as ten years ago we lacked the technical capability to exploit that frontier. Now we have that capability, and if we have the willpower to use it we cannot only benefit all humankind, but also spare our threatened planet and permit its recovery from the ravages of the industrial revolution.8

---

Based on his calculations (which assumed a robust and cost-efficient Space Shuttle fleet), O’Neill thought it quite possible for a space colony to be “in place, with its productive capacity benefiting the Earth, before 1990.”

More recent space advocates have also been insistent that the development of space resources would overcome all resource constraints. Robert Zubrin, in his 1996 vision of Mars colonization, writes: “We can establish our first output on Mars within a decade, using well-demonstrated techniques of brass-tack engineering backed up by our pioneer forebears’ common sense.” Once settled on Mars, the colonists would find the opportunities for growth to be immense: “virtually every element of significant interest to industry is known to exist on the Red Planet.” Eventually, the Mars colonists would venture off to the nearby asteroid belt, where they would find vast mineralogical resources just waiting to be tapped. The ultimate outcome would be a “triangle trade” similar to that which existed between Britain, the North American colonies, and the West Indies during the eighteenth century. In the twenty-first-century version, Earth would supply “high-technology manufactured goods to Mars,” Mars would supply “low-technology manufactured goods and food staples to the asteroid belt,” and the workers in the asteroid belt would send precious metals back to Earth. The new Martian civilization would also be a “hotbed of invention,” producing “wave after wave of invention in energy production, automation and robotics, biotechnology, and other areas.” As a result, Mars colonization “will dramatically advance the human condition in the twenty-first century.”

Space advocates argue that even if such activities eventually deplete the resources of nearby planets and asteroids (an unlikely eventuality for thousands of centuries), humans can simply move on to other solar systems. Carl Sagan suggests that human communities might migrate from planet to planet, exhausting the resources of each before moving on, much as earlier nomadic human communities exhausted local agricultural and animal resources and then migrated elsewhere. “We might call it ‘pioneering’ or ‘homesteading,’” Sagan observes, while acknowledging that “a less sympathetic observer might describe it as sucking dry the resources of little world after little world. But there are a trillion little worlds in Oort Comet Cloud.” Zubrin puts it simply: “The universe is vast. Its resources, if we can access them, truly are infinite.”

The only danger these theorists see, not surprisingly, is the possibility that mankind will fail to grasp the opportunities before it. Zubrin is emphatic that humanity needs to be constantly on the move, constantly growing, or it will stagnate and die:

---

9. Ibid., p. 10.

The key is not to let the process stop. If it is allowed to stop for any length of time, society will crystallize into a static form that is inimical to progress. That is what defines the present age as one of crisis. Our old frontier is closed. The first signs of stagnation are clearly visible. Yet progress, while slowing, is still extant: Our people still believe in it and our ruling institutions are not yet incompatible with it.\(^3\)

There is hope for the future, Zubrin avers, but only if the people act at this crucial movement to reverse decline by opening a new frontier. The stakes, in his view, could hardly be any higher:

The creation of a new frontier thus presents itself as America’s and humanity’s greatest social need. \textit{Nothing is more important:} Apply what palliatives you will, without a frontier to grow in, not only American society, but the entire global civilization based upon values of humanism, science, and progress will ultimately die.\(^4\)

Zubrin specifically endorses the theories of Frederick Jackson Turner, agreeing that what makes America free, egalitarian, and innovative can all be traced to the existence of a frontier. Without a frontier, America will lose those traits. As evidence of decline, Zubrin cites the “increasing fixity of the power structure and bureaucratization of all levels of life; impotence of political institutions to carry off great projects; the proliferation of regulations affecting all aspects of public, private, and commercial life; the spread of irrationalism; the banalization of popular culture; the loss of willingness by individuals to take risks, to fend for themselves or think for themselves; economic stagnation and decline; the deceleration of the rate of technological innovation . . . . ” Despite his purported faith in progress, science, technology, and the American Dream, Zubrin believes that the contemporary United States is in deep trouble: “Everywhere you look, the writing is on the wall.”\(^5\) But he is not too worried since he knows the real explanation for his long list of maladies: the frontier is gone. Once we get it back, all those measures of societal health will reverse direction and start trending upward again. Zubrin is confident of this because he embraces the assumption that all facets of civilization will either rise or decline together as a function of the presence or absence of a frontier experience.

Even the limits posed by celestial threats to Earth can be overcome, space advocates say, but only if we colonize space quickly. Since the 1970s, space advocates

\(^{13}\) Ibid.
\(^{14}\) Ibid., p. 297, emphasis added.
\(^{15}\) Ibid.
have become increasingly fond of justifying space or Mars colonization on the grounds that it is the only means to ensure the survival of the human race in a universe where an asteroid could slam into Earth at any moment. Space advocates emphasize that the dinosaurs became extinct because they failed to master their environment—without a space program, they were left at the mercy of untoward celestial encounters. Such encounters await Earth again in the future, space advocates note, and suitable preparation is therefore required. As Sagan puts it, we live in a solar system marked by “routine interplanetary violence.” He estimates that “[T]he chance is one in a thousand that much of the human population will be killed by an impact in the next century.” It was this possibility that prompted Sagan, long a skeptic of human spaceflight, to finally endorse an active program of space colonization in the near future. He writes: “The asteroid hazard forces our hand. Eventually, we must establish a formidable human presence throughout the inner solar system. On an issue of this importance I do not think we will be content with purely robotic means of mitigation.”

Sagan notes that as humanity spreads to other planets, it will then possess a form of “planetary insurance” against the possibility that an asteroid deflection system might break down or that other catastrophes on Earth might destroy humanity. When life is spread widely, he writes, it can never be killed. Thus, Earthlife will become immortal or at least will find the means to survive as long as the universe itself. In this sense, space advocates see their own agenda as ultimately more life-affirming than any conceivable program of political action on the agenda today. As former astronaut John Young puts it: “Knowing what we know now, we are being irresponsible in our failure to make the scientific and technical progress we will need for protecting our newly discovered severely threatened and probably endangered species—us. NASA is not about the ‘Adventure of Human Space Exploration,’ we are in the deadly serious business of saving the species.”

But, alas, time is short. Although all space advocates will acknowledge that the odds of a massive asteroid collision in the next century are extremely slim, they nonetheless argue for taking immediate steps to establish a permanent human presence in space. Their reasoning is that humanity may be going through a “critical period” in which it simultaneously has the capability both to destroy itself and yet

17. Ibid., p. 264.
also to establish a beachhead in outer space. There may be a narrow window in human history, space advocates argue, in which humanity has the opportunity to move into space. This window has only recently been opened and it may swing shut quite soon, due to the surprise arrival of an asteroid, nuclear war, biological war, or a general societal breakdown. The lesson: Act now, while you can, or forever be sorry. As Sagan writes: “The more of us beyond the Earth, the greater the diversity of the worlds we inhabit, the more varied the planetary engineering, the greater the range of societal standards and values—then the safer the human species will be.”

Thirty years after he first walked on the Moon, Neil Armstrong commented upon the Apollo program’s significance: “The important achievement of Apollo was a demonstration that humanity is not forever chained to this planet. Our visions go rather further than that and our opportunities are unlimited.” In this statement he expressed the abiding faith in an unlimited future that has historically been central to the idea of progress, and which space advocates insist, contrary to a host of critics, remains equally valid today.

All Good Things Go Together

In a review of Enlightenment ideas about progress, political theorist Nannerl Keohane writes: “In its most robust and purest form, the belief in progress affirms that increases in human knowledge, the establishment of human control over nature, and the perfecting of the moral excellences of the species will guarantee one another, with a concomitant increase in human happiness.” But it is precisely this faith, she argues, that “good things come in clusters” that is “the Enlightenment addition to the theory of progress that is most problematical today.” The space advocates, however, are not worried. In general, they see advances in one area—science and technology—as contributing only to advances, not problems, in other spheres of human life. Space advocates cheerfully maintain the old, untroubled conviction that “good” things and ultimate values do not collide but, rather, reinforce each other. The human movement into space, consequently, is not expected to bring any unforeseen problems, but will instead only contribute to massive improvements in other aspects of human existence.

“Space colonization appears to offer the promise of near-limitless opportunities for human expansion, yielding new resources and enhancing human wealth,” concluded a 1977 NASA study on the possibility of space settlements. The study asserted,

The opening of new frontiers, as it was done in the past, brings a rise in optimism to society . . . . It has been argued that it may also enhance the prospects of peace and human well-being. Just as it has been said that affluence brings a reduction in the struggle for survival, many have contended that expansion into space will bring to human life a new spirit of drive and enthusiasm. [The benefits of space colonization will be experienced by all, for] successful exploitation of the extraterrestrial environment is expected to enhance the standard of living not only of the population in space but the population remaining on Earth as well . . . . [The opening of space is so significant that] this new vista, suddenly open, changes the entire outlook on the future, not only for those who eventually want to live in extraterrestrial communities but also for those who want to remain on Earth.24

The NASA authors clearly see this change in outlook as a transformative one—a shift from a negative, cramped view of the future to a vision in which limits are overcome and countless new opportunities are created. The opening of the space frontier, they suggest, will improve human civilization in all respects—not just by bringing economic and technological advancement, but also by enhancing the spiritual, political, and cultural health of all humanity.

Others have argued that the diffusion of human beings off the planetary surface will open up new opportunities for social experimentation—opportunities that were last seen, they suggest, in the original settlement of the New World and the American frontier. “On Earth it is difficult for . . . people to form new nations or regions for themselves,” science author T. A. Heppenheimer observed. “But in space it will become easy for ethnic or religious groups, and for many others as well, to set up their own colonies . . . . Those who wish to found experimental communities, to try new social forms and practices, will have the opportunity to strike out into the wilderness and establish their ideals in cities in space.” In a burst of multicultural enthusiasm, Heppenheimer even suggests that “[W]e may see the return of the Cherokee or Arapaho nation—not necessarily with a revival of the culture of prairie, horse, and buffalo, but in the founding of self-governing communities which reflect the Arapaho or Cherokee customs . . . .”25 Carl Sagan also sees more cultural diversity as humanity establishes new civilizations on different planets and other celestial bodies: “Each society would tend to be proud of the virtues of its world, its planetary engineering, its social conventions, its hereditary predispositions. Necessarily, cultural differences

would be cherished and exaggerated. This diversity would serve as a tool of survival.”

Zubrin likewise claims that Mars colonization will promote cultural diversity in a world where it is increasingly threatened by proximity and overcrowding.

Space migration will also enlarge the pool of positive images of the future available to humanity—images that space advocates consider essential to motivate and guide purposeful activity. Many space advocates complain that optimistic images of the future have been displaced in recent decades by far more negative views. Sagan writes: “Where are dreams that motivate and inspire? Where are the visions of hopeful futures, of technology as a tool for human betterment and not a gun on a hair trigger pointed at our heads?” A rare exception to the spread of gloomy visions, according to Sagan, was the space program of the 1960s: “Apollo conveyed a confidence, energy, and breadth of vision that did capture the imagination of the world . . . . It inspired an optimism about technology, an enthusiasm for the future . . . . With Apollo, the United States touched greatness.”

With a renewed commitment to space, the psychological and cultural health of America and humanity in general would surely improve.

Space advocates also foresee a new era of peace and mutual understanding arising as a result of space travel. Sagan writes that “the unexpected final gift of Apollo” was “the inescapable recognition of the unity and fragility of the Earth.” Sagan continues: “I’m struck again by the irony that spaceflight—conceived in the cauldron of nationalist rivalries and hatreds—brings with it a stunning transnational vision. You spend even a little time contemplating the Earth from orbit and the most deeply ingrained nationalisms begin to erode. They seem the squabbles of mites on a plum.”

Another space enthusiast, Frank White, argues for the existence of what he calls an “overview effect” in which humans who are launched into space achieve a veritable breakthrough in human consciousness:

[Those living in space] will be able to see how everything is related, that what appears to be ‘the world’ to people on Earth is merely a small planet in space, and what appears to be ‘the present’ is merely a limited viewpoint to one looking from a higher level. People who live in space will take for granted philosophical insights that have taken those on Earth thousands of years to formulate. They will start at a place we have labored to attain over several millennia . . . . [Space dwellers will become aware that] we are one; we are all in this together; war and strife solve nothing . . . . [T]he multiplier effect means that sending a

28. Ibid., pp. 171, 174–175.
limited number of people into space can lead to a broad-based social transformation. The experiences of the few become new information for the many, serving as fuel for social evolution.29

Sagan argues that the need to detect and deflect threatening asteroids will encourage the formation of some form of world government. Since the technology needed to deflect asteroids is potentially very dangerous (not least of all because it could be used to send asteroids hurtling into Earth instead of away), it will be necessary to develop much stronger international institutions to develop and control this capability. “The existence of interplanetary collision hazards, when widely understood, works to bring our species together . . . . [T]he small near-Earth worlds provide a new and potent motivation to create effective transnational institutions and to unify the human species. It’s hard to see any satisfactory alternative.”30

With similar esprit, the Planetary Society once stated in its official Web site that it hoped to “reach out into the low-energy universe, investigate and understand its many splendors, travel to and perhaps settle its distant shores, seek those unfound ‘others’ and, in the process, advance the cause of world citizenship here at home.”31 World citizenship: it has that universalistic ring that has informed theories of progress from the very beginning.

The only real impediment to the realization of these noble dreams, Sagan and other space advocate suggest, is the rise of ungrounded fear of science. Writing in the 1990s, Sagan describes a “demon-haunted world” where popular understanding of science is under siege by believers in alien abductions, astrology, crop circles, crystal power, and so on. “We risk becoming a nation of suckers, a world of suckers, up for grabs by the next charlatan who saunters along,” Sagan warns.32 His own message is simple: the more science and technology, the better. Sagan writes: “There’s no turning back from science. Many will have to become scientifically literate. We may have to change institutions and behavior. But our problems, whatever their origins, cannot be solved apart from science.”33 The faith in science is fundamental because the space advocates believe, as believers in progress always have, that science and technology will have predominantly beneficial effects for humanity. Accordingly, moving into space will not have any unintended, negative consequences for either the humans living there or those remaining on Earth.

Sagan sums up the prevailing view with his usual flair: “I think that, after some debugging, the settlement of the Solar System presages an open-ended era of dazzling advances in science and technology; cultural flowering; and wide-ranging experiments, up there in the sky, in government and social organization.”34 Zubrin similarly concludes that “Mars may someday provide a home for a dynamic new branch of human civilization, a new frontier, whose settlement and growth will provide an engine of progress for all of humanity for generations to come.”35 In such words we see a virtually perfect expression of the faith that all good things go together, and that profound and tragic choices between equally valued goals can be easily avoided.

Innate Directionality

Supporters of the idea of progress have usually insisted that there is some kind of mechanism or force—perhaps even a divine force—that keeps history on track, moving it forward toward betterment. In their own revitalization of the idea of progress, space advocates have also identified certain innate developmental tendencies that, in their view, are likely to drive history forward. As has historically been common with theorists of progress, the most popular mechanism is one based on the idea of evolution through natural selection. Sagan suggests that a human expansion into space is ultimately rooted in those traits that tens of thousands of years of natural selection have ingrained in mankind. Humans began as nomadic hunters and foragers, and those who were the most adventurous, who courageously sought new sources of food and water, were the ones who survived. “Even after 400 generations in villages and cities, we haven’t forgotten. The open road still softly calls, like a nearly forgotten song of childhood . . . . This appeal, I suspect, has been meticulously crafted by natural selection as an essential element in our survival.” The exploratory urge is simply built-in to humanity, although not everyone possesses it in equal measure. “Your own life, or your band’s, or even your species’ might be owed to a restless few—drawn, by a craving they can hardly articulate or understand, to undiscovered lands and new worlds.” This is the drive—the causal mechanism—that almost inevitably will eventually lead to an expanding human civilization in space. “We’re the kind of species that needs a frontier—for fundamental biological reasons,” Sagan writes.36 And it is in space, nowhere else, that the best and final frontier can be found.

The same kind of evolutionary reasoning is employed by historian Louis Halle, who writes in Foreign Affairs in 1981 that there is “reason to believe that, in its progressive evolution, life has at last reached the point where it is about to expand into outer space, as if it had been programmed in advance. For, as evolution has a direction,

---

34. Ibid., p. 318.
it has an implicit destiny in that direction; although it may fail to realize that destiny as an infant may be killed by an accident before it had realized its own destiny of achieving adulthood.” Halle specifically endorses O’Neill’s then-popular plan for space colonies, and suggests that the movement into space is functionally similar to the movement of life from the seas onto dry land some 350 million years ago. Wernher von Braun similarly exclaimed that the first Moon landing was “equal in importance to that moment in evolution when aquatic life came crawling up on the land.” Neil Armstrong himself joined in the naturalistic imagery, telling The New York Times that humans must move into space “just as salmon swim upstream.”

Such views typically reveal a classically teleological style of reasoning, so popular in theories of progress, in which all of human history is seen as motivated and guided by an ultimate purpose or final end. This doctrine imputes a certain consciousness and directionality—a telos—to a process that, on the face of it, might seem dominated by arbitrariness and accident. As one critic has noted, such thinkers claim that space migration “must be understood as an evolutionary stage, a natural development, not just comparable to but homologous with the emergence of life on Earth from the water, or the separation of a child from its mother.” It is not surprising, then, that the directionality identified by space advocates often shades off into a prediction of outright inevitability. “Maybe not right now, or next year, or even in 1990, but the space solution is inevitable, and, as shocking as it might at first appear, it is too late to debate the right—or-wrong of it,” former NASA astronaut Bryan O’Leary informs us in his 1981 work, The Fertile Stars. “It is fruitless to make value judgments about whether we should go into space,” O’Leary continues, “whether mining the Moon and asteroids is the right thing to do, or whether we ought to build space shuttles or receive solar power from space—for we are in space to stay.” Still, O’Leary does spend the rest of his book rehearsing the various arguments—both economic and spiritual—for why space colonization should, in fact, be pursued. Much like other theorists of progress, O’Leary is convinced of the inevitability of his dream but sees no contradiction in calling for conscious action to bring about its realization.

In truth, most of the claims of the new pro-space ideology of progress do not withstand critical scrutiny. A massive program of space development and colonization was not and is not a rational response to rising energy costs. There are no known resources at the present time that could be obtained more profitably in space than on Earth. Likewise, arguments that America is stagnating scientifically, culturally, or economically, and therefore needs the stimulus of a major space endeavor have no backing in hard evidence. The notion that a frontier is crucial for freedom or innovation is not a finding accepted by either historians or social scientists. Claims that space travel will broaden human sensibilities, thus reducing nationalist and chauvinist impulses, are about as convincing as the belief, once widely held, that the view from high-flying airplanes would alter consciousness in a more cosmopolitan direction. New forms of diversity and social organization in space might eventually occur, but any effort at space colonization in the near term is likely to involve a degree of regimentation and control that is hardly conducive to social experimentation. The oft-mentioned need to deflect asteroids could be handled effectively by robotic spacecraft or by small piloted missions. And if there is a compelling need for an off-planet civilizational “back-up” source, a small base on the Moon would suffice (no massive colony required). Finally, claims that humanity is programmed to explore the universe fall prey to the fallacy of composition: just because individuals like to explore does not mean that the larger group of which they are a part (in this case, the human race) has a need to collectively explore. As some space advocates themselves point out, history is full of examples of human societies that decided to stay put, choosing to remain within a viable local habitat indefinitely. There is no known innate human tendency that will require human beings to explore space, any more than there is a program forcing humans to settle Antarctica or the sea floor. To the extent that space migration does occur, it will be as a result of conscious human decisions, just as human migration has been in the past.

Without question, then, much of the pro-space literature is deeply flawed.\(^{42}\) Ironically, it is also in tension with other forms of technological optimism. For those committed to the notion that humanity must move into space to survive, signs of growing success on Earth are disconcerting. If advances in biotechnology, artificial intelligence, and nanotechnology allow humanity to prosper on Earth

to a greater extent than ever before, the urgency of the space endeavor is lost. In fact, if one has faith that terrestrial technology will continue to advance, the idea of spending billions of dollars on unprofitable space ventures becomes even less attractive. Why not just wait until new technologies reduce the cost of spaceflight to reasonable levels? At that point, normal market mechanisms (such as tourist demand) may allow major increases in human spaceflight without government intervention. But then, of course, no grandiose ideology of progress will be required, any more than such an ideology was required to populate the formerly arid deserts of the American southwest once water and air conditioning became widely available.

Despite all this, pro-space ideology retains the power that only a full-blown theory of progress can possess. NASA’s own discourse, not to mention that of President George W. Bush and other politicians, frequently invokes the language of progress, with talk of destiny and inevitability, the overcoming or abolition of limits, and the virtuous cycles of knowledge and goodness that space development will surely bring forth. It is reasonable, therefore, to expect that the discourse surrounding space will remain one of the primary expressions of the idea of progress for a very long time to come.

**Conclusion**

The rise of a post-Apollo space advocacy literature, and its integral relationship to the idea of progress that has been at the core of Western civilization, surely counts as one of the more provocative societal consequences of the success of space travel. Although its concerns are currently on the margins of public debate, the potency of the modern space advocacy synthesis suggests that it will continue to draw adherents and influence the thinking of policy-makers. In comparison to earlier doctrines of progress, pro-space ideology is more grandiose, with its vision of planetary engineering and cosmic expansion, yet also more fearful, with its suggestion that the end times may be near if the space frontier is not soon conquered. This peculiar confluence of ambition and anxiety is likely to influence the pro-space movement and the larger debate about the American future in space for many years to come. Given the deep commitment of Americans to ideas about progress, such ideological concerns are as likely to affect policy as any rational assessment of scientific or economic need. As the development of the American space program itself attests, the capacity of the idea of progress to drive politics—and history—in unexpected directions should not be underestimated.
Within the halls of space agencies, common wisdom holds that a space program will inspire young people to study science and mathematics. The word “inspire” has its roots in an old belief that a supernatural spirit could infuse a person with a vision or an insight into truth. Along those lines, one modern meaning concerns fostering creativity. Again, common wisdom in the United States holds that science, mathematics, and engineering are “hard” subjects, to be avoided by anyone who is not “smart.” Even “smart” people see no point in working hard to enter technical professions where the remuneration may not match such fields as business or law. On the other hand, policy-makers at the national level understand that the ultimate competitiveness of the United States is related to its ability to generate and utilize advanced technologies, which requires a workforce educated in science, mathematics, and engineering.

If it is true that a vigorous and exciting space program can motivate a subset of young people to switch to technical studies, then the program will serve a national need. But why should a space program uniquely motivate young people to pursue a technical education? The methodologies of the robotic space science missions do not differ so much from other forms of research, and the explanations of their findings are esoteric. Human space operations are intellectually more accessible to a young person, but few people actually become astronauts.

It is true that people do become passionate about space. We all know the terms “space cadet” and “Trekkie.” Yet, both these terms have origins in entertainment media. Are “space cadets” only a type of groupie, a product of celebrity worship? Although people can also be passionate about hobbies and can be motivated to study to become a specialized expert, space seems to have very catholic appeal over all cultures and genders. Is there something different about space that can motivate people, particularly young people, to form a life plan directed toward involvement at some level in the space program?
Rationales

In 1982 I became the junior member of a Gang of Three whose aim was to initiate discussion within NASA concerning a human lunar base for the era following the low-Earth orbit space station. At the time, NASA had no long-term planning organization, and was focused on getting approval for a space station. Talk of a lunar base was met with indifference if not hostility.

Over the next several years, our advocacy group was successful in attracting interest both within and external to the Agency for discussion of human exploration of the Moon. Within our little cabal, my role usually was that of a spokesman at conferences and workshops. We developed a more or less standard presentation or “pitch” on overhead transparencies. The title chart was followed by a Rationale or Justification chart, containing four to six bullets (talking points) that were intended to convince the audience of the importance and truth of our cause. The Justification chart is required by all managers for project presentations and represents the customer requirements. In an engineer’s ideal world, the Rationale comes down the chain of command, generated at some higher pay grade.

Early in our process, we developed Rationales based on our perception of strategic goals for NASA. As we consulted with a wider audience, we began to adopt Rationales that might address national (or societal) needs. For example, the resources available on the Moon could supplement decreasing inventories of raw materials on Earth. Our presentations worked pretty well with passive audiences, but one-on-one encounters with senior experts on national policy were a different kettle of fish. I quickly learned that any of my naïve generalizations could be savaged by an appropriate authority unsympathetic to the “space solution.” I do not mean to imply that our ideas were bad or wrong, but our arguments needed much more sophistication and nuance.

Within a very few years, my Rationales had moved to grand concepts such as humanity moving into the solar system, or intangibles such as inspiration of youth. Many essayists and professional authors have written about the space program in terms that express the broadest human issues. While NASA was formulating the response to the 1989 speech by President George H. W. Bush in which he outlined his Space Exploration Initiative, a number of philosophical discussions took place over how the space program serves the nation; some engineers were very uncomfortable talking about unquantifiable “requirements.”

As the lunar base movement became more widespread prior to that presidential speech, I became identified in some quarters of the space community as a leading advocate for settling the Moon. Consequently, I received invitations to speak at a number of events, particularly those sponsored by space activist groups. The audiences were thrilled with artist concepts of lunar facilities and loved to hear what kind of activities would take place on the Moon. The agendas of these conferences always included discussions of the “message” needed to encourage more spending on space programs. I noted that the advocate groups brainstormed to generate rationales for space investment, to be expressed in bullet format on charts.
Epiphanies

Individual conference attendees always expressed a great passion for space activities and carried a vision of a future where living in space was commonplace. Over the years I also became aware that many, if not most, of them could tell a story of some specific event in their lives that marked the beginning of their intense interest in space exploration and development. People said, for example, “I bought a science fiction book to read at Girl Scout camp, and I have been interested in space ever since.” “When I was five years old, my dad told me to come downstairs and watch men walking on the Moon.”

As I was absorbing this information, my wife was taking training to become more involved in evangelism for her Lutheran church. I heard portions of training videos with discussions about Christian outreach. I noted certain similarities and differences between the two advocacies. In both cases, congregations hear sermons expressing certain truths upon which they all agree. In both cases, people inside the movement cannot understand why everyone is not part of their belief system. In both cases, the group concludes that outsiders simply lack the facts.

The two communities differ dramatically in their form of outreach. The church encourages individual Christians to explain to outsiders how their lives have been changed for the better through adoption of the church’s belief system. In fact, many Christians believe they have had transformational experiences—epiphanies, if you will—that have changed their lives, and they tell the unchurched that similar experiences will be accessible if they enter into the Christian belief system. On the other hand, space advocates believe that their conclusions are based on reasoning, and some of them use the overhead chart with Rationales. Their success is limited.

I wondered whether many space advocates also had had their interest awakened by some inspirational experience. If so, it would suggest an outreach strategy based on involving more people in space activities in a personal way. Presumably, opportunities would present themselves from which people would discover an interest in a space future.

Frank White has written of an “overview effect” experienced by astronauts on orbit from which they experience a profound change in personal perspective toward life. I am not convinced that the overview effect is an example of a space-derived epiphany I am thinking about. Rather, I associate it with a kind of perspective alteration associated with extreme experiences, such as a brush with death or personally witnessing for the first time grinding poverty or deep suffering.1

I had an opportunity to take a step toward exploring this hypothesis at the 2003 meeting of the International Lunar Exploration Working Group (ILEWG) in Hawaii.

---

ILEWG

In 1989 President George H.W. Bush launched his Space Exploration Initiative (SEI), which charged NASA with returning to the Moon to stay and journey onward to Mars. NASA composed a reply with scenarios for future human exploration missions and hired a new Associate Administrator for Exploration by the name of Dr. Michael Griffin. By 1992, the SEI was politically dead in the United States and NASA had a new Administrator by the name of Dan Goldin. For space pundits in the United States, that was that.\(^2\)

However, other nations had reacted to the U.S. initiative. The European Space Agency (ESA) produced a collection of studies of potential scientific investigations on the Moon, which led to a technical session at the World Space Congress in 1992. In 1994, ESA convened a workshop on a future lunar exploration and development strategy in Beatenberg, Switzerland. At that workshop, the Japanese delegation offered to host a subsequent topical workshop in 1996 in Kyoto, Japan.

After the Beatenberg event, the NASA Associate Administrator for Science proposed an International Lunar Exploration Working Group (ILEWG) to the Interagency Coordinating Group (IACG). The 1996 Kyoto workshop was convened as an ILEWG meeting. Much to the surprise of many of the attendees, the Japanese presented a large number of papers on future lunar exploration plans, including the first official announcement of the SELENE mission. (The lunar orbital scientific spacecraft, recently renamed Kaguya, will finally be launched in 2008.) However, a scientific finding suggesting evidence for past life in a Martian meteorite had been announced only two months before. NASA Administrator Goldin was looking past the Moon toward Mars. One of the official NASA representatives to ILEWG in Kyoto gave a rather lengthy commentary on reasons to forget about the Moon and focus on Mars.

After Kyoto, official NASA representation disappeared from ILEWG. Although meetings were held, the group became more of a gathering of lunar exploration advocates than a true interagency coordinating body. However, the Japanese were still treating ILEWG as a recognized body and ESA continued to fund travel for a few representatives. Dr. Bernard Foing of ESTEC (the European Space Research and Technology Centre, which is the design hub for most ESA spacecraft and technology development, and is situated in Noordwijk, The Netherlands) became a major advocate for ILEWG and eventually was named Project Scientist of the ESA Smart-1 lunar technology mission.

---

Steve Durst, head of Space Age Publishing and a long-time advocate of human settlement of the Moon, offered to host the 2003 ILEWG gathering at his home base in Hawaii. I attended the meeting, but NASA sent no official representative. Dr. Michael Duke sat at the table as the senior U.S. presence, but he had retired from NASA. On the other hand, Indian representatives attended, and the Chinese Space Agency tried to send a large delegation. No Chinese actually attended because they could not obtain U.S. visas. The usual small number of Japanese and European delegates were there. The remainder of the attendees included various lunar scientists, advocates, students, and a few space celebrities, such as astronaut John Young, invited by Durst. The good attendance possibly had something to do with the attractive venue in Hawaii. I have known Steve Durst for more than 20 years through his interest in lunar development, and I also knew almost all the senior people at the meeting because the list of usual suspects in the lunar advocacy community is not large.

One of the luncheons at the meeting was sponsored by the aerospace company SpaceDev and its founder, Jim Benson, was the featured speaker. I have heard Jim speak several times, and he often begins by pulling out his 1955 membership card from the Science Fiction Book Club, where he encountered the writings of Isaac Asimov and was “turned on” to space. Jim was trained as a geologist and by chance entered the computer software industry in its early days. He later sold a successful software business and used the money to start SpaceDev as a company to build small spacecraft for planetary science missions. Here was another of my space stories.

At the next luncheon, two young people spoke about their interest in the Moon. One was Yuki Takahashi, who had contacted me a year or two earlier with a great passion to build a telescope on the Moon. He went from an undergraduate degree at Caltech to a doctorate program in astrophysics at the University of California at Berkeley. At one point he and I exchanged e-mails about his desire to abort his studies in astrophysics to work somewhere on a lunar telescope project. (I urged him to complete his doctorate!) At the luncheon, he spoke of a trip to a library with his parents in Japan at age 9. He discovered there an entire encyclopedia on astronomy. He devoured it and became absorbed with the idea of space exploration. Here was another of my space stories.

At an afternoon break that day, I rudely grabbed the microphone from Steve Durst and told the people in the room that I wanted them to help me with an experiment. I briefly explained my idea about transforming experiences triggering an interest in space. At the hotel meeting room, every seat had a small notepad and a pen. I asked them to use the notepad to first answer the question, “Did you have a specific event in your life that you remember as catalyzing your passion for space?” I asked them to write Yes or No on the pad. If the answer was Yes, I asked for a brief description of the event. I also asked for the person’s age at the time of the event and the person’s current age (at the time of the meeting in 2003).
DATA

I eventually received 50 submissions. Adding Benson and Takahashi and myself, I have 53. I forgot to ask for gender, but six submissions are clearly from women. Current ages (in 2003) start at the early 20s. I have four from men older than 75. In the text below, I include three figures that are scans of actual submissions to me in order to illustrate the style and informality of typical responses.

Three submissions (including my own) simply answered in the negative. Everyone else wrote a few words of explanation. Seven of them declared no real moment of “awakening” but elaborated on the beginnings of an evolution of interest. Two men grew up in families involved in the space program or space science and just followed their parents into the field. Another man has a stepfather who flew helicopters that picked up astronauts after landing in the water. That memory dates from when he was 8 or 9 years old.

A man (I presume) states that he had no epiphany but remembers lying on his back, looking at the summer sky, and talking about the stars with his friends at age 10. He joined the high school astronomy club. After a B.Sc. in physics, he eventually acquired a doctorate in economics while maintaining a lifelong interest in astronomy. Although he enters himself in the “negative” column, his commentary is not qualitatively different from that of another man, who writes simply, “Astronomy merit badge Age 14.” The latter submitter presumably intended that brief statement to indicate an event that brought him into the space community.

A woman who denies having an “epiphany” nevertheless mentions that “[T]he movie Contact did inspire me to want to continue our space exploration efforts for the pure scientific joy if nothing else.” A 22-year-old woman who responded positively to the question recalls a transient interest after watching the movie Space Camp when she was about 8 years old.3 However, she attributes her current involvement to learning at age 16 that “a family member was involved in Apollo 11.”

A native Hawaiian woman writes: “When I was a small girl, maybe 3 or 4 years old, I noticed the moon would follow me wherever I went. Obviously, the moon liked me. It even would follow me home and wait near my house for me to come outside . . . . So I decided she was my friend and always looked forward to seeing her.” How this cultural view of the Moon evolved into attendance at a space conference is not explained. Another woman who describes herself as “a non-American female” writes: “I used to watch the Moon & stars with my father and he & my brothers used to tell me about astronauts, etc. when I had to go to sleep. So I always wanted to dedicate my life to space exploration. I am now 30 years old. And as far as I can remember I always looked up to the Moon & the stars.”

A 42-year-old man denies any single event but adds, “I think that generally Rocket Launches are the thing that drives [sic] my interest the most.” Another man, born in India but now a U.S. citizen, describes his triggering event as: “1963—six years old(.) Nike-Apache sounding rockets blasting off from Thumba Equatorial Launching Station (TERLS) in Trivandrum, India.” For both, rocket launches are a common focus, but one writer sees them as triggering his interest in space whereas the other doesn’t.

One interesting catalyzing event was mentioned by a 29-year-old from the Netherlands: “I never had a specific moment to determine my interest. [It] has always been there. However, I never believed that I could do something with it. Until [sic] I helped organize a conference (1998), then my life changed and got more direction to where I am now [sic].” Here a person believes he went from a passive to an active role through volunteering to organize an activity.

Among those who responded positively to the basic question, certain themes are repeated. Three (older) people mention Sputnik. Many inputs reference early human missions, particularly Gemini and (of course) Apollo. A tale of Gemini 8 is reproduced as figure 30.1.

The Apollo 11 first step on the Moon is listed by several. One woman’s memory of Apollo 11 is reproduced here as figure 30.2.

Figure 30.1—Here, a person was energized by a pre-Apollo human mission. Note the comment about leaving space studies after Apollo. Many people were disillusioned by the cancellation of the Apollo program by President Nixon.

Figure 30.2—The first human landing on the Moon is widely considered to be an iconic event in the history of civilization. Not surprisingly, many people recall it as memorable, often mentioning watching the first lunar step with family.
For a man, Apollo 17 was the most important. His memoir:

Launch of Apollo XVII, December 7, 1972

- I was 6 years old in the first grade.
- I had never stayed up so late to watch TV.
- I remember NBC’s program theme music for its coverage of the mission.
- I met Gene Cernan when I was 12.
- I will meet Jack Schmitt this Thursday.

Steve Durst’s daughter, who was a graduate student at the time of the ILEWG meeting, writes that she was raised in a family that talked about space a great deal. However, her personal interest was catalyzed by the LDEF mission, a technology experiment that returned various material samples to Earth after exposure to the low-Earth orbit environment for five years. For Ms. Durst, the most interesting returned cargo was tomato seeds that were distributed to schools for planting.

A 38-year-old man cites a three-hour chat across the aisle on an airplane flight with Tom Stafford at age 28.

A 48-year-old man by chance heard Jim Lovell speak in Hawaii at a convention two years before this survey. The writer is president of a construction company who came to the ILEWG meeting to learn more about construction on the Moon.

Books, particularly science fiction books, are important, especially around ages 8 to 15. Verne, Heinlein, Asimov, Wells, and Clarke are all mentioned. Figure 30.3 is a memorable submission. However, not only science fiction was important; Yuki Takahashi mentioned the encyclopedia of astronomy. Jack Green, a prominent pre-Apollo proponent of lunar craters as calderas and 78 years old at the time of this survey, writes, “1945 publications of J. E. Spurr on lunar volcanism.” A Jet Propulsion Laboratory (JPL) technologist recalls the time “My Mom gave me a section of the Chicago Tribune with an article by Dr. Dan Q. Posen on space.” A woman writes: “When I was in 5th grade (10 or 11 years old), I had a class in the school library where we learned about the Dewey decimal system. It was so boring that as I sat on the floor, I read the books I was seated next to. That happened to be the 523 section that contained the Astronomy books. I knew I was hooked when I read them all!”
A (now retired) internationally recognized scientist, who was one of the top leaders in the Apollo scientific studies, writes: "My parent bought me a book which still sits in my bookcase, ‘The Omnibus of Jules Verne’, which had both books ‘From the earth to the moon’ and ‘Around the moon.’ I was 11 years old. I was not aware at the time of a transformation. However, I realized during Apollo 16 that ‘I had been there before’—and quickly found the page in the book which contained the specific paragraph which gave me that certainty.”

Visual media also play a role. Carl Sagan’s Cosmos series is mentioned three times. Interestingly, no one mentioned the classic Disney series from the 1950s that featured Wernher von Braun, although I noted above two women who identified specific movies. A man writes, “My interest in space came when I was about 5 years old; I saw the movie ‘The Conquest of the Moon’ in 1955.”

The last recurring category is astronomy. Inputs already cited mention looking at the sky or reading books or achieving a merit badge. There are those who received telescopes from their parents or visited observatories. It has been known for a long time that widespread public interest in astronomy makes that subject a good way to introduce scientific concepts.

**Discussion**

My question to think about an epiphany may have seemed strange, but I was pleased by the enthusiastic reaction. Approximately 80 percent of the responders believed they had something to say. Even those who claimed to have nothing to say often added commentary. Several thanked me for the opportunity to write down their experiences.

On the surface, nothing in these notes is new to those familiar with the space program. There are many different paths to an interest in space, yet no one describes his or her involvement in the form of a reasoned argument. Two prominent lunar geologists come closest. One was a graduate student in geology, napping one day when a fellow student pounded on his door to tell him the Russians had “launched a 180 pound satellite.” The other geologist was a young Ph.D. who “watched Neil and Buzz step onto the Moon” and “shortly thereafter . . . saw my 1st Apollo 11 rock.” The fact that so many people found my question interesting rather than bizarre and that such a large percentage remember their first awareness of space suggests an emotional attachment, which is part of what I was seeking. A next step would be to ask these responders to elaborate on their vision of humanity’s future in space. Launch technology evolves so slowly that they might not actually see themselves in space.

I chose the word epiphany deliberately because I find the passion behind many peoples’ interest in space to be almost religious in nature. (I am not the only one to notice this.) I have encountered many individuals or groups who have some transcendent vision of future activities or assets in space. This basis for these beliefs becomes a particularly
important issue today because the vision of an economic sphere in cislunar space and on the Moon has become an element of national policy and a little-understood element of the President George W. Bush’s Vision for Space Exploration initiative. Traditionally, people who believe in a private economy in space have been belittled by the space establishment such as NASA employees or major aerospace contractors. The latter argue that there is no business for major investors beyond government contracting.

Today, of course, we see a new phenomenon whereby so-called high net worth individuals (HWNIs) are investing significant amounts in ventures to build new launch systems, space vehicles for tourism, and even a hotel. Robert Bigelow has committed $500M million of his personal fortune to build an orbiting facility and has already launched the first test module. If the business case is so weak, why are these people in the game? I suggest that they are “believers” who happen to have the money to pursue their dreams.

**CONCLUSIONS**

This simple, serendipitous sampling suggests that further studies by professionals in social science might prove interesting. However, one must remember that this particular meeting was convened by a visionary with the stated purpose of discussing future activities on the Moon, and the attendees may well be self-selecting for this kind of survey. We may be looking at a subculture rather than the space movement as a whole.

In 1995 in Stockholm, Sven Grahn of the Swedish Space Corporation and I led a team project titled “Vision 2020” at the summer session of the International Space University (ISU). About 40 young space professionals from a variety of countries and a variety of disciplines volunteered to be part of an attempt construct a vision of what space activities would be important 25 years into the future. As leader of the exercise, I went to great lengths to avoid providing structure that might suggest the “right answer” to the students. We worked with an academic in Future Studies to employ visioning, a technique for creating desirable future scenarios. The lack of structure given to the students had the unfortunate effect of producing a lack of structure in their deliberations. When time came to present an outline of the final product to the ISU faculty, the presentations seemed unimaginative.

5. The alt.space community has enjoyed considerable positive publicity. An example of this is Elizabeth Weil, *They All Laughed at Christopher Columbus: An Incurable Dreamer Builds the First Civilian Spaceship* (New-York: Bantam Books, 2002).
I chaired a faculty meeting to provide feedback to the students. Sitting in on the meeting were about half a dozen ISU alumni who were in town for the annual Alumni Weekend. The faculty criticism was savage. I took notes and struggled to understand how I might communicate the feedback in a constructive way. However, one by one, the alumni began to assail the faculty, accusing them of being part of a bygone and obsolete “Apollo generation.” The young people claimed that space programs of today were not built around grand visions but should be directed to benefit the quality of life on Earth—a theme that was being carried within the project. Clearly, there was a generation gap in expectations in this exercise.

When one looks around the world, one can see space projects aimed at disaster management or provision of services to the population or scientific investigation. The grand structure of the Vision for Space Exploration initiative stands out for its bold assertion of a potential future society in space. Is this just a U.S. cultural product, or is it really a more generally held vision? I personally find a response to the vision around the world, but I believe more study of societal response to visions of a future space civilization is important to the promoters of these policy goals. I must leave such studies to professionals in the social sciences.
CHAPTER 31

Alexander C.T. Geppert

The only interplanetary voyages made by our species to date have been flights of fancy.

A.V. Cleaver
British Interplanetary Society
11 October 1947

HISTORICIZING THE EUROPEAN SPACE EFFORT

Historians need to explore . . . the cultural meaning of space exploration, and the space programs of other countries” besides those of the United States, American scholar Pamela E. Mack has suggested. Since she made this statement in 1989, i.e., almost 20 years ago, the state of research in Europe has gradually, yet not absolutely, improved. The publication of the official history of the European Space Agency (ESA), on the occasion of its 25th anniversary in 2000, certainly marked a milestone in this process. In much detail and on more than 1,100 pages,

1. A.V.Cleaver, “The Interplanetary Project,” Journal of the British Interplanetary Society 7, no. 1 (January 1948): pp. 21–39, here p. 21. This paper presents the first findings of a comprehensive research project on the cultural history of outer space, astrofuturism and extraterrestrial life in the European imagination of the twentieth century, approximately between the publication of Hermann Oberth’s pioneering Die Rakete zu den Planetenräumen (1923) and the establishment of ESA a half-century later (1975). I would like to express my sincere gratitude to the editors of this volume for their kind invitation to me to discuss parts of my work at such an early stage, and to the Fritz Thyssen Stiftung for generously supporting this Habilitationsprojekt. Heartfelt thanks are also due to Dorothee Dehnicke, Rita Hortmann, Heinz Hermann Koelle, Tessa Mittelstaedt, and Paul Nolte.

this multinational institution’s complex beginnings and the development of its organizational structure were meticulously traced back to the formation of its two precursors, the European Launcher Development Organisation (ELDO) in 1962 and the European Space Research Organisation (ESRO) in 1964, while deliberately leaving aside broader social, cultural, and imaginative issues. What is true for the history of Europe at large, however, is applicable here as well: European history and the history of Europe are not identical, but overlap at best. The in-depth analysis of a single European institution—thoroughly researched and, without the slightest doubt, enormously valuable as it now stands—should not be taken for a social and cultural history of European practices and representations of outer space per se. In other words: Because it lacks a direct equivalent to the NASA History Office and the Space History Division of the Smithsonian National Air and Space Museum—with their concerted activities and unparalleled research programs which effectively created and later shaped the entire field in the United States—in Europe, space history is a much smaller, more fragmentary, and by far less established area of historiographical research.

In direct consequence, much research on the cultural history of the European space effort, its historical significance, and societal impact still remains to be done, especially with regard to the 12 years after Peenemünde and prior to Sputnik—a period which many consider the Golden Age of Space Travel avant la lettre. Therefore, the following tentative reflections are limited to presenting and discussing three broader issues and provisional hypotheses. They are intended to ask the right questions rather than to provide possibly premature answers. First, where do historians have to look in order to locate what kind of possible repercussions of spaceflight? Why is it so complex a task to identify and measure any kind of impact spaceflight might have had on culture and society in general? Second, how can Europe’s role and position in this entire scenario be described and assessed? Has a distinctly European version of outer space evolved gradually, especially since 1945? Or were, for instance, the Apollo flights already subject to

3. John Krige, Arturo Russo, and Lorenza Sebesta, A History of the European Space Agency, 2 vols. (Noordwijk, The Netherlands: European Space Agency Publications, 2000). “Little has, in fact, been written on the European space effort,” the authors conceded in their preface, and went on to ask for “more reflective and comparative studies” to contextualize their results and to relate them to other research in the field (vol. 1, p. xvi). Walter A. McDougall, “Space-Age Europe: Gaullism, Euro-Gaullism, and the American Dilemma,” Technology and Culture 26, no. 1 (January 1985): pp. 179–203. For a recent fact-oriented summary of European activities in outer space, see Brian Harvey, Europe’s Space Programme: To Ariane and Beyond (Chichester, U.K.: Springer-Praxis Publishing, 2003); see also ESA’s own historical series, called History Studies Reports. The most recent of these more than 30 working paper-type publications are to be found at http://www.esa.int/esapub/pl/history.htm (accessed 17 January 2007).

such globalized, carefully orchestrated, and extensive media coverage that they subsequently gave rise to the same process of myth-making both in the United States and in Europe? And, third, while the persistence of the so-called American spacefaring vision has, time and again, been attributed to the deeply rooted frontier myth in popular culture and in the public imagination, is the European vision of outer space best characterized by the complete lack of such a key trope and the absence of a commonly shared belief system—or is there any equivalent?

“Berlin, wir haben ein Problem,” (“Berlin, we have a problem”) read one of the most popular slogans in a recent national advertising campaign, entitled “Deutschland braucht Raumfahrt” (“Germany needs spaceflight”). Financed by the German space industry, this campaign lamented the lack of government support and endeavored to raise public awareness of the industry’s pecuniary needs and oft-formulated appeal for increased government funding (figure 31.1). It is more than remarkable that such a tribute to the famous Apollo 13 phrase “Houston, we’ve had a problem”—originally uttered by Commander James Lovell in April 1970 but popularized by Tom Hanks in the Oscar-winning Hollywood blockbuster 25 years later—did not require an explanation, even in a German context, proving to be sufficiently effective in an entirely different public sphere. Apparently, the responsible publicity agency had every reason to take for granted the existence of the necessary historical background information. The well-informed spectator would be rewarded with a smile for his successful knowledge transfer from one national context to another and applying it to quite a different problem. In the present academic context, however, this witty motif draws our attention to the potency of American popular culture myths far beyond national borders, where, in fact, they may be interpreted quite differently. In the end, “Berlin, wir haben ein
Societal Impact of Spaceflight

The “problem” points to the far-reaching importance of international and crosscultural perspectives in analyzing both science fact and science fiction. It reminds us, in short, that the societal impact of spaceflight and its imaginative dimension cannot be properly historicized without considering transatlantic references, perceptual interdependencies, and transnational interrelations.

SPACEFLIGHT, THE IMPACT QUESTION, AND THE SPATIAL TURN: THREE HEURISTIC REMARKS

Without going into too much detail, the first heuristic remark consists of a fundamental conceptual question: How can we define—and then diagnose—the societal impact of spaceflight in an historical and international perspective? How do we describe, assess, and characterize it once such impact has been recognized? And what set of criteria do we employ in order to compare views and attitudes toward space and spaceflight across different cultures worldwide?

The challenging aspect of this question lies, of course, in the paradigmatic inversion and the complete change in historiographical perspectives it proposes. For a long time one of the most fundamental questions in the field of space history was how spaceflight, in a comparatively short time, developed from science fiction into science fact. Who invented the necessary technologies, where, and in what circumstances? What kind of institutions were established, who financed them, and how did they produce, structure, and organize knowledge? Which scientific fictions became, at what point, predominant and were transformed into actual science—whereas others remained merely fictitious? Today, historians seem far less interested in compiling yet another, sometimes semi-hagiographical, often oversimplistic, yet almost always teleological genealogy of space travel thought, its pioneers, and its practitioners. The new perspective is diametrically reversed. It is also less prone to endorsing undercomplex master narratives. What was formerly the dependent variable now becomes the independent one. We take spacefaring as given, and then aim to understand and explain the impact and possible effects that outer space, space travel and space exploration have had on culture and society at large.

From the viewpoint of a cultural historian and recent newcomer to this field of historical research, such a general change of perspective seems more than overdue. Almost inevitably it should lead to less specialist and fewer internalist analyses, to the advantage of broader, more integrative perspectives, by paying greater attention to historical context and culturally ascribed meaning. Multifaceted links and manifold connections are conceivable if space history breaks with its self-chosen splendid isolation and decides to open itself up to different historiographical branches such as social, cultural and intellectual history, but also to less obviously related disciplines such as science studies, social and cultural geography, sociology of knowledge, literary criticism, art history, and contemporary archaeology. Most probably, such an extension will eventually lead to a complete transformation of the entire field and
enable space history to harmonize far better with presently “hot” historiographical debates on transnationality, globalization, and “entangled history” as the key features of a state-of-the-art histoire du temps présent.5

At the same time, space historians must remain cautious. “Impact” is a very broad and imprecise term that can denote many different aspects simultaneously. Space-related cultural artifacts, such as Hermann Oberth’s seminal 1923 book Die Rakete zu den Planetenräumen and Frith Lang’s 1929 film Frau im Mond, certainly had an immense public impact; so had Willy Ley’s numerous public lectures and Wernher von Braun’s countless media appearances, not even to mention the actual events such as the Sputnik launch in 1957, the first weather satellite launch three years later, the Mercury and Gemini flights, or the Apollo landings which, in many ways, marked the end of an epoch rather than the beginning. After defining and refining the original “impact question,” space historians thus need to sharpen their analytical tools by differentiating carefully between different kinds of impact, and by endeavoring to categorize, classify, and contextualize. Whom or what was affected, when and where, immediately or on a long-term basis? And did this impact have a lasting effect or did it fizzle out soon after? Different notions such as “repercussions,” “influence,” “consequences,” and “effects” on the one hand, and “perception,” “reception,” “consumption,” and “appropriation” on the other, come to mind and could be considered possible alternatives.

Conceptual problems of an almost identical kind are by no means specific to this field of historical research. They have been discussed by neighboring disciplines and branches of research—such as reception aesthetics—at least since the 1970s, if not even earlier. Quite clearly, this constitutes another good reason why space history can only profit from widening its thematic focus and sharpening its analytical tools, including the incorporation of innovative methodological achievements made elsewhere.6

Moreover, in order to locate and specify societal and cultural impacts of spaceflight and space exploration, it might prove necessary to search elsewhere, in areas where effects, consequences, and repercussions are not readily expected and hence are

Societal Impact of Spaceflight

less obvious than, say, in utopian literature, pop culture, or science fiction TV shows and movies. If the implicit assumption of this volume is correct—that spaceflight was, at least for several decades during the twentieth century, an emblematic and absolutely central element to the project of Western modernity—historians should be able to locate evidence for its lasting effectiveness far beyond the established circles of the international spaceflight community and their widespread activities, and as independently of its historical and contemporaneous advocates as possible.

Last but not least, it is somewhat surprising to observe that the notion of “space” itself has hardly been problematized and how little theoretical attention it seems to have received, despite the classic works by geographers, philosophers, sociologists, and ethnographers such as Gaston Bachelard, Henri Lefebvre, Yi-Fu Tuan, Pierre Nora, Marc Augé, and numerous others. How can we explain that the current upsurge of interest in space as a specific category of historical analysis—which is frequently labeled topographical or spatial turn—and the historiographical field of space history have not at all been seen in relation to each other so far? “What are you buying when you go to outer space?” someone asked rhetorically during the conference which inspired the present volume, and then replied to his own question, seemingly surprised, by exclaiming in despair: “There is simply nothing there!” Yet, outer space is by no means a spatial vacuum; it changes constantly and is always formed and refashioned. It is precisely this static and ahistorical notion of space that must be problematized by asking questions such as: “Where” and “what” was outer space at which point in time? How was it represented and imagined? Has the perception of space changed over time? And in what way were changing conceptions in turn affected by the continuous and ongoing exploration of outer space? Even if it may sound paradoxical, it would seem high time to apply the so-called spatial turn to space history, and to write a social and cultural history of outer space with special emphasis on: space.

Europe’s Outer Space in the Postwar Period: 1945 and 1968/69 as Global Turning Points

Is there a genuinely European variant of outer space? In fact, is there a specific perspective on outer space which could be called European? Is there a set of commonly shared assumptions about space and the specific role of Europe in the history

---

of spaceflight? For the period prior to 1945 at least, these questions are not highly problematic. Historians agree as to the fundamental significance of the various European space fads of the 1920s, notably in Germany and Russia, and, in consequence, the far-reaching effects of the slow yet steady formation of various interconnected networks of international space experts. Also in other European nations, such as Great Britain or France, transnational personal contacts among rocket scientists and space experts frequently preceded the establishment of the various amateur societies.9

Yet, by the time the Golden Space Age was in full swing in the 1950s—with actual space travel remaining far from a reality—Europe’s position was secondary at best. Hence, the crucial question in this context is precisely when and through which unilateral transfer processes such cultural hegemony was lost in the aftermath of World War II, not least as a concomitant of the rapidly emerging U.S.–USSR polarization. Analytically, the problem is further complicated by the fact that many of the new key players then residing in the United States, such as the engineer and rocket scientist Wernher von Braun (1912–1977), the writer and space science popularizer Willy Ley (1906–1969), and the technician Krafft Arnold Ehricke (1917–1984), were clearly of European origin, even if they may have gradually developed a somewhat different attitude concerning their own nationality. Von Braun, for instance, did not participate in any of the early international congresses on astronautics which began in Europe annually after 1950, and did not (even temporarily) return to Germany prior to the autumn of 1957.10 Be this as it may, with regard to Europe’s (self-)positioning vis-à-vis outer space, the end of World War II was definitely the first decisive turning point whose long-lasting impact can still be felt today.

Indications of this fundamental displacement of cultural hegemony can, for instance, be observed in the realm of popular culture, especially with regard to imagery and iconography. More than 10 years after its 1929 premiere, film stills originally produced for Fritz Lang’s epochal *Frau im Mond* were used time and again to illustrate numerous articles on rocketry and spaceflight appearing in a wide array of international journals and magazines, simply due to the lack of visual material otherwise available.11 By the early 1950s, however, the situation had drastically changed.

---

At that time, a direct equivalent to the enormously successful *Collier’s/ Disney* complex simply did not exist in any European context. Popular iconography widely available in the European public sphere was far less elaborate, less futuristic, and by no means as imaginative as its American counterpart—just compare, for instance, the visual expressiveness of Chesley Bonestell’s (1888–1986) famous illustrations for *Collier’s* magazine with a number of European samples from the same period (figures 31.2 and 31.3). The first example, showing a spaceship on the Moon with its crew about to begin their exploration, was distributed by the British Interplanetary Society to its approximately 2,300 members as their official Christmas Card for 1952; the second stems from one of the numerous publications of Heinz Gartmann (1917–1960), a German engineer, author, and well-connected editor of *Weltraumfahrt: Beiträge zur Raketenentwicklung*, and was based on a painting by graphic artist Klaus Büergle (1926–). It is hardly surprising that these illustrations proved far less effective and by no means as trendsetting as their American counterparts.

On the other hand, the lavishly illustrated, large-format books into which the American *Collier’s* series had swiftly
been transformed were soon translated into numerous foreign languages, including Japanese, Italian, Dutch, Swedish, Finnish, German, French, and Spanish, and sold especially well in Europe. In Germany, for instance, S. Fischer, one of the best-reputed publishing houses, soon acquired the copyrights and, before long, sold a considerable number of copies, running into several thousands. Thus, geopolitical and iconographical shifts went hand in hand. From a European perspective, the 1950s space race was accompanied by a new sociocultural spacefad in the public imagination, although this time of transatlantic rather than domestic origin.

Ever since then, autonomy—or, rather, the quest for it—has been the predominant theme of the European space effort. Since the first “philosophical” reflections, undertaken by the Italian physicist Edoardo Amaldi (1908–1989) in April 1959, on the urgent need to establish an official and independent European space organization, “encouraging” or even “increasing” European unity “from without” has been the explicit political aim in all common activities in space. In the late 1980s five European research institutes came to the conclusion that a European “space spirit” had gradually developed, largely as a consequence of ESA’s activities. They argued that to undertake such activities would give the European Union (EU) nothing less than a genuine chance to “consolidate a common identity.” The EU, they concluded in their large-scale study, should hence have its “eyes and ears in space.” Steadily pursuing this goal has, at least at times, posed a considerable challenge to all plans of cooperation with third parties and possible partners such as the United States.

Christmas 1968 marks the second, well-known turning point, with the epoch-making spaceflight of Apollo 8 and the first photographs of the entire Earth taken on this occasion. American writer Archibald MacLeish (1892–1982) and Austrian philosopher Günter Anders (1902–1992) were among the first to realize that the most profound consequence of the Apollo program was not at all the continued exploration of outer space, its scientific results, or the proof of the actual technical possibility for doing. It was, rather, a radical change in self-perception on a genuinely global level, literally resulting in a new Weltanschauung, i.e., ways of viewing the world. For the first time ever, it was felt that the entire Earth could be seen—and see itself—from without and as a whole.\footnote{Archibald MacLeish, “A Reflection: Riders on Earth Together, Brothers in Eternal Cold,” \textit{The New York Times}, 25 December 1968: p. 1; Günther Anders, \textit{Blick vom Mond: Reflexionen über Weltraumflüge}, 2nd ed. (München: C. H. Beck, 1994), p. 12: “Das entscheidende Ereignis der Raumflüge besteht nicht in der Erreichung der fernen Regionen des Weltalls oder des fernen Mondgeländes, sondern darin, daß die Erde zum ersten Mal die Chance hat, sich selbst so zu sehen, sich selbst so zu begegnen, wie sich bisher nur der im Spiegel sich reflektierende Mensch hatte begegnen können.”}

Even if this argument, originally coined by MacLeish and Anders simultaneously but independently of each other, has been repeated and modified so many times since that it now might be considered trite, it is beyond doubt that the images originating from this particular mission (especially the famous photograph “Earthrise”) produced enormous, hitherto entirely unforeseen effects. It is no exaggeration to state that these images fundamentally altered our contemporary geographical imagination. Thus, the major television event of the 1960s, the 1969 Apollo Moon landing, must, first and foremost, be seen as a carefully orchestrated, global media event. The fact, that it could be witnessed by approximately 600 million people, i.e., approximately a fifth of the world population, live on TV in 49 countries worldwide, symbolizes the central role of space exploration in the process of globalization. Taking place only seven months after Apollo 8, it was cause and effect at the same time: Technically only possible because of the recently set up Intelsat system, the Moon landing proved an event which, in itself, had considerable globalizing consequences difficult to overestimate in retrospect. Not only does this second turning point afford a perfect example of how the exploration of outer space substantially affects and alters conceptions of “inner,” (i.e., Earthly) space, it also makes the question of Europeanness even more complex.\footnote{See, for instance, Frank White, \textit{The Overview Effect: Space Exploration and Human Evolution} (Boston: Houghton Mifflin, 1987); Wolfgang Sachs, “Satellitenblick: Die Ikone vom blauen Planeten und ihre Folgen für die Wissenschaft,” in \textit{Technik ohne Grenzen}, Ingo Braun and Bernward Joerges, eds. (Frankfurt am Main: Suhrkamp, 1994), pp. 305–346; Denis Cosgrove, “Contested Global Visions: ‘One-World,’ ‘Whole-Earth,’ and the Apollo Space Photographs,” \textit{Annals of the Association of American Geographers} 84, no. 2 (June 1994): pp. 270–294; Denis Cosgrove, \textit{Apollo’s Eye: A Cartographic Genealogy of the Earth in the Western Imagination} (Baltimore, MD: The Johns Hopkins University Press, 2001); Andreas Rosenfelder, “Medien auf dem Mond: Zur Reichweite des Weltraumfernsehens,” in \textit{Medienkultur der 60er Jahre: Diskursgeschichte der Medien nach 1945}, vol. 2, Irmela Schneider, Torsten Hahn, and Christina Bartz, eds. (Opladen: Westdeutscher Verlag, 2003), pp. 17–33.}
The same tension—a certain form of nationalism or Europeanness on one hand, versus a specific variant of internationalism or globalism *avant la lettre* on the other—was already a central element in many of the programmatic self-descriptions of the early space advocates, often proving a highly problematic issue. Directly after its inception in 1934, members of the British Interplanetary Society, for instance, discussed their self-image as expressed in the Society’s name on several occasions. Although it was at first disputed whether British Rocket Society would not be a more appropriate name than British Interplanetary Society if it was to harmonize better with its Continental and North American sister organizations, 17 years later, in 1951, the conflict had become whether the word “British” should not be omitted completely from the its title. Some of the Society’s members strongly feared that it could be interpreted as an expression of just that kind of latent nationalism which they considered as contradictory to the Society’s international character and detrimental to their common “vision of the coming of interplanetary communication.” From their perspective, Europe was a state in between two different stages of development. Europe was to be preferred to any national context and something of a self-evident frame of reference, yet not the global society either, which they hoped eventually to create through their cosmic activities.\(^\text{16}\)

**INFINITE FRONTIERS, COSMIC VISIONS, FUTURES PAST**

“The desire to explore and understand is part of our character,” President George W. Bush declared on 14 January 2004, announcing his new “Vision for Space Exploration” initiative at NASA Headquarters in Washington, DC. “Mankind is drawn to the heavens for the same reason we were once drawn into unknown lands and across the open sea,” he continued, in order to justify space travel by making bold psychological statements and indicating broad historical parallels: “We choose to explore space because doing so improves our lives, and lifts our national spirit. So let us continue the journey.”\(^\text{17}\)

---

individual with collective psychology, history with the future, and questions of the quality of life with the welfare of the entire nation. He also reintroduced one of the oldest and most frequently advanced arguments for investing extensive resources in human spaceflight: outer space as humankind’s final frontier, as an enormous, quite natural task only to be undertaken by all concerned collectively, yet obviously and exclusively under his direction and leadership.

By no means was George W. Bush the first to envisage the exploration of outer space as a direct consequence of America’s alleged predisposition to continuously open new frontiers and steadily seek new discoveries. Originally, this famous argument goes back to historian Frederick Jackson Turner (1861–1932) who, on the occasion of the epochal World’s Columbian Exposition 1893 in Chicago, had tried to explain that many characteristic features of American society developed during the exploration of the American West and later persisted, even after the actual process of conquest and settlement was long completed. Turner’s so-called frontier thesis has, ever since, been attacked by legions of professional historians who have severely and successfully criticized his argument from various angles, eventually debunking the thesis as a myth. It was, nevertheless, successfully politically exploited in the 1960s in order to strengthen unity and the nation’s self-image by conjuring one great common task. Thus, Bush did not add a new element to the debate but, rather, took over and gave fresh justification to exactly the same kind of frontier rhetoric that numerous other space advocates, including John F. Kennedy and John Glenn, had already used long before him, and in which current NASA Administrator Michael Griffin also seems willing to invest.

Whether true or not, from the perspective of a professional historian it is quite remarkable how present a simplified and vulgarized version of Turner’s original thesis still is in everyday public discourse, and what considerable influence it continues to have in the American public sphere. It might be best described as an historical argument of the second order, i.e., an argument that is historically far from accurate but is retrospectively believed to be true and, despite its original falseness, thus proves enormously effective (in this case, up to the present day). When applied within a European context, its shortcomings become even more obvious. Although Europe

has always had a variety of different and oft-changing frontiers and open spaces, both real and imagined (most of which were located overseas), a direct equivalent to the American frontier has never existed, neither in Realgeschichte nor in myth. Even more than in the United States, some time in the early 1970s the theme of “space” lost much of its popular and futuristic appeal, as did nuclear power and atomic energy.20

From the aftermath of World War II through the early 1970s, however, outer space clearly had constituted one of the “major sites of utopian thinking,” not only in the United States but also in Europe.21 During these three decades it was a widely shared assumption that the future would—literally—take place in outer space. While also fostering actual technological developments, scientists, technicians, and engineers drafted grand schemes of how the world would soon appear. They attempted to anticipate a future in space and at the same time tried to interpret and make this understandable from a philosophical perspective. Some of the main protagonists, such as the English science-fiction author Arthur C. Clarke (1917–), philosopher Olaf Stapledon (1886–1950), aeronautical engineer A. V. Cleaver (1917–1977), and the already mentioned technician Krafft A. Ehricke (1917–1984), considered themselves explicitly as agents of an ongoing spatial revolution—the “interplanetary project”—which would change humankind forever. Long before Sputnik they already declared the advent of the “Space Age” or the “orbital age,” featuring an “interstellar” or “multi-planetary society” peopled by “Homo extraterrestris” or “interplanetary man,” and diagnosed the dawn of a new “3-dimensional civilization.” They discussed potential repercussions of spacefaring on the human psyche, demanded the establishment of a United Nations organization control, and debated with great verve not only whether “on Mars life (such as we know) has evolved to the human level” but also how communicative exchange with extraterrestrials might be made possible. Reflecting upon the necessity for a “common field of semantic reference (C.F.S.R.)” as a condition for any exchange between Earthlings and their “extra-terrestrial neighbours (E.T.N.),” under the heading of “Astraglossa” some enthusiasts even set out to take “first steps in celestial syntax,” just in case genuine long-distance communication “with beings with whom we presumptively share no idiom of discourse” had to be initiated (figure 3.4).22

Controversies on the existence of extraterrestrial life are by no means an epiphenomenon of postmodernity; they go back at least to the Copernican revolution. Even if early experts such as Willy Ley, Wernher von Braun or the numerous members of the German Gesellschaft für Weltraumforschung (GfW), under the direction of engineer Heinz Hermann Koelle (1925–), often did their very best to steer clear of such muddy waters and preferred, mainly for tactical and strategic reasons, not to take an openly positive stand, the quest for extraterrestrial life has always been one of the most central, yet often hidden, motives behind many scientific debates and space-related enterprises; not surprisingly, it still is today. It is not a coincidence that so many contemporary space exploration projects are motivated by the search for water, believed to be a necessary precondition for extraterrestrial life-forms.

Ultimately, it can be argued that a vast number of the debates fought out during the twentieth century on the social and cultural rationale behind the space effort oscillated between two distinct poles—or, as it were, “discursive vanishing points”—other than the myth of the frontier. First, there is that entire argumentative strand for which literary scholar De Witt Douglas Kilgore has found the neat label “astrofuturism,” i.e., the widely shared belief system that the future would necessarily take place in outer space and that it would entail an encounter with alien life-forms as the twentieth century’s most radical version of imagined alterity but yet an “other” unlike any other before.24 A German journalist summarized expectations for the future in 1951: “The steady progress of science and technology obscure the boundaries. More than ever the world of tomorrow is a concern of the present, and even to visit a secret laboratory can today become the beginning of an adventurous voyage of discovery into the future.”25

Second, in addition to this utopian component there is a strong religious, spiritual, and/or mythical strand to be detected behind these numerous debates and activities. How did changing images and conceptions of outer space, “other worlds,” and the entire cosmos impinge not only on competing versions of the future but also on religion and transcendental beliefs? As early as the late 1920s, contemporary critics spoke of the “religion of spacecraft,” calling it a “technological ersatz religion.” Although such an aspect continues into the present, it has hitherto not been adequately examined, sometimes quite dramatically so. Both factors—the utopian/futuristic strand and the spiritual/religious component—must be made central categories when historicizing outer space.26 Last but not least, it is Archibald MacLeish and Günter Anders who deserve credit for drawing our attention to the anthropocentrism so deeply inherent in all variants of space exploration. They made us realize that the Copernican revolution never took place in the realm of the imaginary. The more elaborate and far-fetched our conceptions and images of outer space, of other worlds “out there,” and extraterrestrial life-forms have become, the more anthropocentric they remain. Indeed, distinguishing between space exploration and its impact can only constitute a temporary analytical separation. In fact, spaceflight already affected European culture and society long before it ceased to be a mere “flight of fancy.”

Section VII

Afterword

~
Recall the figure at the end of Section 4.2.
Are We a Spacefaring Species?
Acknowledging Our Physical Fragility as a First Step to Transcending It

M. G. Lord

In a preface to *The Man Who Sold the Moon*, a 1950 collection of short stories, Robert Heinlein emphasized that science-fiction authors do not generate “prophecy.” They write speculative fiction, a riff on the notion of “What if?” Often they invent alternative realities to critique aspects of the world in which they live. Yet our aspirations to become a spacefaring species—and our assumptions about our abilities to do so—were defined by science fiction, from the cannon-ball-shaped spaceship that blasted off in Jules Verne’s 1865 fantasy *From the Earth to the Moon* to the canonical stories and screenplays produced by various authors—Ray Bradbury, Isaac Asimov, Frank Herbert—during the Cold War.

What interests me is the disparity between who we are in our imaginations and who we are in real life. In fiction, we have mastered extraterrestrial flight; our technology enables us, to quote a classic split infinitive, “to boldly go” anywhere. In reality, however, we are fragile creatures that do not thrive outside Mother Earth’s atmosphere, gravity, and magnetic field. In the last 40 years, robotic scouts—many designed and flown by NASA’s Jet Propulsion Laboratory (JPL)—have sent home tantalizing glimpses of new worlds. In the next 40 years, we ourselves will strike out for these worlds—planets many times more distant than our Moon, worlds truly apart.

Engineers have demonstrated the know-how to build a craft that will transport a crew to, say, Mars. But there is a catch. In recent months, biomedical researchers working in relative obscurity have begun to raise a big unanswered question: Can the human body withstand a prolonged journey into deep space? The constraints imposed by our biology could have profound societal implications. What does it mean to our collective dreams if a major obstacle exists to realizing them? And how much risk—as well as financial expenditure—will society tolerate in their pursuit?

---

Galactic cosmic rays are the “dragons” that lurk beyond Earth’s magnetic field, the biggest threat to human spaceflight. And they are not just of concern to a few Chicken Littles. They trouble, for example, Shannon Lucid, the plucky astronaut who spent 223 days, 2 hours, and 50 minutes in space, the longest stint of any American woman. “Radiation could be a showstopper,” she said.2

This is a far cry from the way radiation appeared in literature at the dawn of the space program. In Americans into Orbit, a 1962 book aimed at young readers, radiation was simply one more hurdle that a can-do astronaut could easily surmount.3 No air in space? We’ll take it with us. No gravity? We’ll spin the spacecraft and make some. And to reverse the decline of muscle and bone caused by weightlessness, we’ll lash ourselves to a treadmill and break a sweat.

In 1961, Marvel Comics writer Stan Lee and artist Jack Kirby actually cast radiation as benign, suggesting it could produce positive mutations. After exposure to a solar flare during the flight of an experimental spacecraft, the Fantastic Four—scientist Reed Richards and his fellow astronauts—morphed into crime-fighting superheroes: Mr. Fantastic, the Thing, the Human Torch, and Invisible Woman (who back then was called Invisible Girl).

Perhaps the fiction most responsible for the dream of safe, easy travel was Robert Heinlein’s Rocket Ship Galileo, a 1947 tale of two boys who, with the help of one boy’s scientist uncle, cobble together a rocket in their back yard and blast off for the Moon. Nearly every engineer I interviewed for Astro Turf, my recent book on JPL, recalled Heinlein’s impact, as did many of today’s space entrepreneurs: X-Prize founder Peter Diamandis, XCOR chief Jeff Greason, and even SpaceShipOne financier Paul Allen.

Heinlein was not unaware of radiation, and he knew it could cause mutations. But he, too, cast them as benign. His character Joe-Jim, for example, a two-headed beefcake who leads a mutant army in Universe (1951), is none the worse for his genetic anomaly. If anything, because Joe-Jim has the thinking power of two brains, he is better.

What exactly is a galactic cosmic ray and why does it pose a threat? It is a high-energy heavy ion that originates from an exploding supernova outside our galaxy. Such atoms travel very fast, about the speed of light, and they are said to be “ionized,” meaning that they have gained or lost electrons. As a consequence, they carry a positive or negative charge. They can be any element up to the atomic weight of iron. We don’t encounter them on Earth because our atmosphere protects us. Likewise, the Earth’s magnetic field, which extends beyond the atmosphere, functions as a shield—except for a small, quirky patch of orbit over Brazil known as the “South Atlantic anomaly,” where it does not.

2. Interview with Shannon Lucid, Johnson Space Center, 5 June 2005.
Are We a Spacefaring Species? Acknowledging Our Physical Fragility as a First Step to Transcending It

One might expect lead—that familiar prophylactic against dental x-rays—to provide shielding. But a lead “shield” actually compounds the problem. When a heavy ion strikes an atom of lead, it dislodges a cascade of charged particles that can cause destruction similar to that of the heavy ion.

Think of a cosmic ray as “a bullet flying around with speed and mass,” Marcelo Vazquez explained. He is a researcher at Brookhaven National Laboratory on Long Island who studies the effect of radiation on brain cells and other tissue. “When the rays go through matter—it can be a rock, a body, or your brain—they produce so much energy and charge that they produce a kind of hole. But they also produce secondary particles, like a shower.” These secondary particles are called delta rays.

Hydrogen compounds offer the best protection against secondary particles because hydrogen atoms contain one electron for one proton. The current best solution for a Mars-bound ship is an aluminum or carbon-composite shell, with 2 to 4 inches (5 to 10 cm) of polyethylene (a hydrogen compound) around the crew compartment. Water is another efficient shield. But nothing—not even an artificial electromagnetic shield around the spacecraft—will block the rays entirely.

Shielding matters because cosmic rays kill brain cells (or, in any case, brain cells in vitro). In Vazquez’s laboratory experiments, cosmic rays induced what is called programmed cell death in neurons. The bombarded brain cell assesses its degree of damage and decides to die rather than try to fix itself. Moreover, as a heavy ion passes through a column of cells, it forms a “track,” which you can see in the microscopic image in figure 32.1. Dislodged particles career out from this track, inflicting yet more damage on adjacent tissues.

---

4. Interview with Marcelo Vazquez, Brookhaven National Laboratory, 10 November 2005. All Vazquez quotations are from this interview; some of Vazquez’s observations are cited in M. G. Lord, “Impossible Journey,” Discover (June 2006): 38–45.
Vazquez has written papers calculating the amount of brain cells that will be struck by cosmic rays on a two-and-a-half year voyage beyond the Earth’s magnetic field—in other words, on a Mars trip as it is currently conceived by NASA planners. Depending upon the size of the cell, we estimate that between 13 percent and 40 percent of brain cells will be hit once by cosmic rays . . . . We have billions and billions of cells in our brain. But 40 percent is a lot. Some areas are very tiny, but they play an important role in functioning. If you wipe out those cells, you don’t need to worry about the hundreds of billions of cells. A few million—you’re gone. [Alzheimer’s patients lose about 5 percent of their brains annually.]

Radiation, we know from studying atomic bomb survivors, put people at risk for long-latency soft-tissue tumors. But, Vazquez pointed out, leukemia can develop more quickly, in as few as two years, raising the possibility of a severely brain-damaged, fatally sick astronaut barely limping back to Earth.

Of course, what happens to cells in vitro does not always reflect what happens in the body, where optimists hope repair will be possible. “To go from Petri dishes to humans is a big jump,” Vazquez said. But his experiments on animals do not bode well for astronauts. Rats exposed to cosmic rays, as well as rats exposed to conventional radiation, showed major impairment of motor skills, measured by their ability to move around in a box. Over a period of 11 months, the rats exposed to x-rays and gamma rays recovered some of their lost coordination, but the rats exposed to cosmic rays appeared never to recover.

On the bright side, NASA scientists believe they have solved one major radiation problem: solar particle events. These are sudden bursts of hot plasma that periodically spew out at high speeds from our Sun. When astronauts return to the Moon, they will most likely tour its surface in a vehicle equipped with a solar-particle shield. Or they will carry equipment for building a temporary storm shelter—a concept that will also work on Mars where, because the planet is farther away from the Sun, astronauts will have more time to secure refuge. The most acute problem remains chronic exposure to cosmic rays.

Not only does chronic radiation exposure hurt people, it also degrades the drugs used to treat them. The antibiotics NASA currently uses on Shuttle missions (Bactrim, Cipro, and Augmentin) lose their potency after about two weeks in space, according to Lakshmi Putcha, a pharmacotherapeutics researcher at the Johnson Space Center. If Mars-bound astronauts equipped with these drugs in their current formulations became ill, she said, “We would have no way of treating them.”

5. Lord, “Impossible Journey.”
6. Interview with Lakshmi Putcha, Johnson Space Center, 7 June 2005.
The problem of drug degradation, however, is not insoluble, and its resolution could come through chemical engineering—coating the active ingredients of a drug with a substance or material that will preserve its effectiveness. For example, lidocaine (an anesthetic used on the Space Shuttle) is suspended in water—a radio-resistant substance—so it tends not to degrade in flight. Dosage for astronauts is also a hit-and-miss affair, particularly for substances ingested orally. Gastrointestinal motility slows down in space and it takes longer for medications to be absorbed.

Space medicine is a long way from the ideal projected in *Star Trek: Voyager* where a holographic doctor, the Mark I Emergency Medical Hologram, performs nifty repairs without ever making a cut. Indeed, laparoscopic surgery, because it does not release buckets of blood, is well-suited to microgravity. Astronaut and medical doctor Dafydd Williams and Mehran Anvari, a Canadian scientist specializing in telerobotic surgery, have been experimenting with telerobotic medical techniques that might be used at, say, a Moon base. But because of the 20-minute lag for radio signals between Earth and Mars, telerobotics will not be of much use to a crew on Mars.

Space medicine must advance before a Mars flight because the human body—even one belonging to a robust astronaut—is extremely vulnerable in space. In a test on an early Shuttle mission, astronauts were pricked on the arm with various antigens, to which they showed diminished immune response. Latent viruses also express themselves in space. NASA microbiologist Duane Pierson has published several papers documenting the presence in astronaut saliva of various viruses, including Epstein-Barr, which has been linked to human mononucleosis. Other common latent viruses could be yet more uncomfortable if they reactivated on a long spaceflight—chicken pox, for example, which usually returns as shingles. And no data exist on whether antiviral drugs, such as acyclovir, work in flight.

The main issue, which NASA scientists have been unable from their current data to determine, is: Does the immune system remain severely depressed, or, in the words of NASA immunologist Clarence Sams, does it “adjust to a new normal?” Some researchers are optimistic that if they could collect data throughout the mission, instead of merely at takeoff and landing, their results might be different. But stress of the sort experienced by, say, researchers in Antarctica also degrades the immune system. And radiation is a big wild card, which may intensify the weakening. Vazquez was blunt in his assessment of a Mars mission: “No matter what you do, you put a guy in a can for six months and it’s a big stress.”

Skeptics often ask, Why bother to leave Earth? Science fiction answers that question with a bigger question, a question that has haunted human society since its first members looked skyward: Are we alone in the universe?

---

7. Interview with Dafydd Williams, Johnson Space Center, 6 June 2005.
8. Interview with Duane Pierson, Johnson Space Center, 7 June 2005.
9. Interview with Clarence Sams, Johnson Space Center, 7 June 2005.
In the 1980s, NASA began a ground-based program, the Microwave Observing Project, to address this question. It involved a systematic sweep of the heavens with radio telescopes. The project was of immense concern to scientists, artists, theologians—just about everyone but former Senator William Proxmire, who tarred it with his “Golden Fleece” award for wasting public money. In 1982, Congress cut the project’s funds, but the public’s yearning for an answer was more powerful than Proxmire’s scorn. Privately financed, the sweep continues.

Robots also seek evidence of life. At JPL, the mission architect’s mantra—“Follow the water”—is code for “Find clues linked to life.” In 1976, scientist Carl Sagan was involved with Project Viking, the Martian probe that some scientists hoped would detect traces of life. Such a wish, however, was never made explicit. Nor was it gratified, which may have led Sagan to fulfill it through science fiction. Nine years later he published Contact, a novel describing a fictive alien encounter.

Scientists approach the hunt for life with a mixture of hope and dread, their expectations molded by science fiction. Hope is inspired by the aliens who came in peace; dread, by those who waged war. The film The Day the Earth Stood Still (1951), directed by Robert Wise, is a hopeful classic; benevolent aliens try to stop us from destroying ourselves. They stand in sharp contrast to the weapon-toters who touched down in H. G. Wells’s War of the Worlds (1898). And I find it hard not to view Robert Heinlein’s The Puppet Masters (1951), about an invasion of parasitic extraterrestrial slugs, as a prescient book. In one scene, scientists view a map of this country. Its central states are designated “red”—indicating the residents’ brains have been taken over by alien slugs.0

The most interesting fantasy, however, involves the commingling of human DNA with that of a benign alien species—the subject of Octavia Butler’s Xenogenesis Trilogy, whose first volume, Dawn, appeared in 1987. Butler, an idiosyncratic loner, may not consciously have sought to comment on the zeitgeist, but her theme reflected the times. With the Cold War nearing an end, Americans were less paranoid about the alien, or—to strip away a metaphor—the communist “Other.”

In contrast, at the height of the Cold War, alien motives were highly suspect. Arthur C. Clarke’s Childhood’s End (1952) is a chilling fantasy of alien “Overlords” who dupe us into relinquishing our autonomous future. Perhaps the funniest—and the cruelest—comment on our eagerness to trust was a 1962 television episode of the Twilight Zone adapted by Rod Serling from a short story by Damon Knight. Titled “To Serve Man,” the show introduced an extraterrestrial race devoted to advancing human health and agriculture. All that human cryptographers know about this race is the title of what appears to be their bible: To Serve Man—which, as it turns out, is a cookbook. 11

---

Since the beginning of the Cold War, gender roles have also been rethought. No longer, for instance, is the idea of women astronauts ridiculed as it was in 1962, when scientist Wernher von Braun responded dismissively to a question about women in space. His boss at the Agency, he quipped, might allow room on a future mission for “110 pounds of recreational equipment.”

Curiously, during the Cold War, when the private lives of American engineers were often rigidly sexist, the science fiction they consumed explored unconventional gender identities. Heinlein, for instance, was almost subversive in the way he proselytized for women as equals, anticipating the careers of astronauts such as Shannon Lucid. “Delilah and the Space Rigger,” his short story from 1949, featured a woman engineer who coeducates an all-male space station, transforming her misogynistic boss into a cautious feminist because her presence increases productivity.

But at odds with fiction is this troubling fact: Women are in certain ways less suited than men to long-duration space travel. Breasts and ovaries are vulnerable to radiation-linked cancers in ways the prostate, for example, isn’t. And women’s metabolisms are different. Promethazine, NASA’s motion sickness drug, takes longer to reach a level of effectiveness in women. Women also tend to show more orthostatic intolerance—light-headedness after getting up from bed or being in space.

Walter Sipes, a Johnson Space Center psychological researcher, believes a mixed-gender crew may have psychosocial advantages on a Mars trip. But women will have to ask themselves: Is this worth the risk?

In an e-mail sent in September 2006, Vazquez reminded me that solutions to the radiation problem will mostly likely not come exclusively through engineering. They will also be operational and medical, and they will always involve minimizing rather than eliminating risk.

Francis Cucinotta, chief scientist of NASA’s radiation program, explains his Agency’s goal: Limit an astronaut’s radiation exposure so that his or her likelihood of developing cancer will be no more than 3 percent greater than that of an average person. Astronauts, as a result, wear dosimeters to monitor the radiation they receive during flight. But the 3 percent is a murky number because data on soft-tissue cancer formation, gleaned largely from atom bomb survivors, are imprecise. Likewise, the dose rate, the type of radiation, and the differences between the populations exposed play a role in computing probability, as do individual dietary, environmental, and genetic factors.

15. Interview with Walter Sipes, Johnson Space Center, 7 June 2005.
16. Interview with Francis Cucinotta, Johnson Space Center, 9 June 2005.
These are some solutions that might make for a safer Mars trip:

1. Travel faster to reduce exposure. Power the spacecraft with a nuclear reactor placed far away from a well-shielded crew compartment.

2. Surround the spacecraft with an artificial magnetic field—an engineering solution that has not yet proven feasible.

3. Surround the crew quarters with a shield of water—currently impractical because of the expense of getting an immense weight, or mass, of water off the Earth.

4. Ingest foods or drugs that shield against radiation. The flavonoids in blueberries and strawberries have antioxidant properties. They don’t yet protect the brain from radiation, but in 30 years there may be a breakthrough.  

5. Finally, send a bunch of aging space cowboys. If, after 10 years, astronauts in their seventies developed cancer, one could hardly say they were struck down in the prime of life. “My kids said that NASA should send me to Mars,” Shannon Lucid joked. “They said, if NASA would send you when you’re 80, Mom, then you could live up there, do something, and they wouldn’t even have to worry about bringing you back.” Of course, with the nearest emergency room 30 million miles away, NASA had better make progress on that holographic doctor.  

The most radical solution, and the one with the greatest societal impact, however, may involve genetic engineering. In defiance of the odds, some atom bomb survivors have not developed soft-tissue cancers. Scientists need to examine their genetic material to determine why; Resistance to radiation would be a strong asset to an astronaut on a long-duration mission. Because of concerns over the medical privacy of astronauts, it’s currently illegal to screen a crew based on genetics, but this might change for a Mars mission. Or, in the more distant future, a private agency could grow radio-resistant astronauts through the miracles of genetic engineering—an idea with a science-fiction precedent.

Gattaca, a 1997 movie written and directed by Andrew Niccol, describes a space program in which astronauts are chosen based on genetic superiority. In the movie, this is a bad thing. The hero is a love child, not the product of a eugenics exercise. Yet the hero’s short-term triumph—securing a spot on a desirable space mission—may seem less admirable if his weak genes expose him to a fatal illness. In the 1970s, in vitro fertilization procedures were uncommon as well as ethically suspect. Today they are performed frequently and not considered an ethical problem. Likewise, other eugenics procedures that are not approved today may become commonplace in the future.

17. Vazquez discussed flavonoids during his 2005 interview cited earlier.

At an International Space Development Conference in Los Angeles in May 2006, I chatted informally with some people from the Space Frontier Foundation. We discussed space tourism—the fact that engineer Burt Rutan’s suborbital spaceship and Los Vegas entrepreneur Robert Bigelow’s orbiting hotel, things that science fiction writers had forecast, were hurtling toward reality.

When Heinlein’s 1955 novel *Tunnel in the Sky* came up, however, some space fans said things that disturbed me. In expressing their desire to emulate the novel’s characters, they failed to make a distinction between plausible reality and fantasy. Set in the future, the novel deals with a group of high school students taking a survival test who end up stranded on a hostile planet. One of the kids who weathers the ordeal returns to Earth but later goes back to the planet with other settlers to found a colony.

I understand the allure of space settlement and share a passion to achieve it. But there is no “tunnel in the sky”—a safe passage without radiation to distant worlds. On Mars, the preferred destination of today’s settlers, there is no magnetic field to shield people from cosmic rays. The most disturbing comment I heard in a space settlement workshop was “When are we going to see babies born in space?” Not soon, I hope, given the damage cosmic rays are known to cause to genetic material.

Robert Zubrin, the engineer-founder of the Mars Society who favors a trip to Mars with Apollo-era technology, has pooh-poohed the threat of radiation. In a 2003 letter responding to a *New York Times* article on space radiation, he pointed out that astronauts who spent months in Earth orbit have not been debilitated. Yet oddly, he did not adequately consider the fact that low-Earth orbit is within the Earth’s magnetic field, and Apollo astronauts never spent more than a couple of weeks outside it.

John Charles of the NASA Space Life Sciences Division seems to have a firmer grip on reality. “Lots of internal discussion is going on now about what level of risk is acceptable for trips like the Mars flight,” he told me, and added,

What is it going to mean in terms of real-world manifestations, including: What is the likelihood of losing a person—having somebody die on a trip to Mars? We may have a case where they only have so much morphine and so many antibiotics so if somebody’s really sick, do you just keep pumping them full of morphine that somebody else might need tomorrow? Or does something else have to happen? And what that something else is, we all dance around because nobody wants to talk about it . . . . We constantly remind each other that our examples

would be people like those who settled the North American continent. [When they struck out for the West], they weren’t planning on coming home. If they got sick along the way, somebody buried them.

Astronauts have a different relationship to risk than normal people. I got my first sense of this reading the Astronaut Ten Commandments on a Web site for Astronaut Hopefuls (or As Hos, as they call themselves). “Keep your weaknesses to yourself,” says Commandment Three. “If you don’t point them out to others they will never see them.”

This sense was confirmed when I raised cosmic-ray concerns at a recent dinner in Hollywood. An astronaut visiting the host rolled her eyes dismissively. “Doctors have been wrong in the past,” she said. “They used to think you couldn’t swallow in space.” And here sat one astronaut, she assured me, who would leap for a spot on a one-way Mars mission.

Public perception, however, is another story. This has profound implications for society. Society must determine, through public discussion, how much risk it is willing to tolerate or, in any event, how much it is willing, through tax dollars, to underwrite. I’m not sure a federal agency should use public money to place civilian astronauts at high risk. Soldiers maybe, but not civilians. The burgeoning private space industry may best accommodate those who choose to place themselves in extreme jeopardy. According to Federal Aviation Administration guidelines, a tourist on a suborbital flight, for example, does not have the same assurance of safety as a passenger on a commercial airline. He or she understands and chooses the hazard. Likewise, explorers on a privately funded space mission could imperil themselves in any way they want, irrespective of society’s disapproval.

This evaluation of risk reminds me of the way scientists discussed cosmic rays in the 1970s and of the unusual means by which a controversy about high-energy heavy ions was resolved. When a heavy ion passes through an astronaut’s head, the astronaut sees a burst of light. This is called a retinal flash. Astronaut Buzz Aldrin first reported the phenomenon in 1969, when he returned from the Moon, but scientists studying cosmic rays had anticipated it. In the early 1950s, University of California at Berkeley biophysicist Cornelius Tobias posited a link between cosmic rays and such visual fireworks. In 1970 (a time when guidelines for experimenting on oneself were more lax than they are today), Tobias placed his own head in the path of a high-energy heavy ion. He wore a black hood when the beam sliced through him; ambient light, he feared, would distort his perception. Tobias believed

20. Interview with John Charles, Johnson Space Center, 6 June 2005. All Charles quotes are from this interview.
strongly that he would see a pyrotechnic streak, and what he saw would confirm his thesis. The experiment accomplished this and more: “It was as if I were looking into the universe itself,” he said.22

I hope the optimists are right: that the human body can survive chronic exposure to cosmic rays. I hope our flesh does not forever curtail our dreams. But to prove this, the optimists might, in the manner of Cornelius Tobias, have to place themselves in the line of fire. And unless society becomes dramatically less risk-averse, they might have to do it on their own dime, without popular support.

In 1956, philosopher Hannah Arendt delivered at the University of Chicago a series of lectures entitled “Vita Activa.” She reworked these reflections, yielding the classic *The Human Condition*, published in 1958. In these works, Arendt’s organizing question centered on whether the Western experience in the previous two centuries might confound rather than aid in working through the challenges of a “modern world . . . born with the first atomic explosion.” She argued that historically ingrained modes of economic and cultural life had created “a theoretical glorification of labor” and “a factual transformation of the whole of society into a laboring society.” As labor ascended as a social organizing principle, ends rather than means guided value judgments, the practical overshadowed the theoretical, and (enlisting a pairing from classical philosophy) action (*vita activa*) trumped contemplation (*vita contemplativa*) as a principle of self- and community-attainment.

In “laboring society,” Arendt claimed, the very intellectual resources we needed to judge, weigh, and direct our technical creations had withered. Events such as the “first atomic explosion” signaled that thought and “know-how” had “parted company for good,” and that we risked becoming “helpless slaves, not so much of our machines as [that] know-how, thoughtless creatures at the mercy of every gadget that is technically possible.” In this concern, she drew on more than a century of social and political critique of the fusion of science, technology, industrialization, and capitalism—the influences of Marx and Weber are prominent, and Heidegger and Mumford loom just offstage. To this quartet of historical vectors, she conjoined

2. Ibid, p. 6.
3. Ibid, p. 5.
stepped-up postwar levels of advertising and mass consumption to reinforce her claims about the scope and entrenchment of a “laboring society.” Collectively, these deep cultural transformations held “great political significance”—not only in terms of the decision making of nation-state elites but also as a rupture among citizens, increasingly disinclined and unable to assess, weigh, and manage their circumstances. Her narrative, thus, fit into a well-developed genre of alienation in modernity; of new modes of social being conditioning human consciousness in ways that threatened the quintessentially human; and of technological supplanting humanistic values.

As historians interested in spaceflight, what might catch our eye about Arendt’s analysis and this literature of sociological and philosophic critique? One fact I have withheld. In that short interval between her Chicago lectures and their revision as *The Human Condition*, Sputnik occurred, and in her prologue to the book it becomes the dominant symbol of this condition of alienation. Sputnik, viewed through the Arendtian lens, was neither sui generis nor an exclamatory act in the superpower-centered geopolitical drama of the cold war. It was, rather, a manifestation and symbol of deeper structures of economic and cultural order, an analysis deriving broadly from Marxian sociology (in distinction from Marxian politics).

This blend of theory and historiography provides the vantage for this essay. Marx’s sociology often is seen with a hard, deterministic slant (“[T]he hand mill gives you society with the feudal lord; the steam mill society with the industrial capitalist”), but is used here less rigidly and as a methodological injunction: In assessing the “social” in spaceflight, look for the relations between modes of production (often with emphasis on the economic) and the cultural. This mantra

---

8. Marx’s notion of culture, of course, was not that of the post-World War II academy in the West. For a classic, brief etymological essay on “culture,” see Raymond Williams, *Keywords: A Vocabulary of Culture and Society* (New York: Oxford University Press, 1976). On Marx’s notion of culture and its relation to the broader genealogy of the concept, see Michael Denning, *Culture in the Age of Three Worlds* (London: Verso, 2004).
is intended only as a point of orientation. As analytical terms, “production” and “culture” run at the edges, embracing different elements, with different meanings, in different contexts. They only get life and clarity through historical specificity. For the historian, an Arendt-type or Marxian sociological analysis carries a burden: Details of difference and situatedness yield to the bright line-making of theory. Despite such semantic and methodological liabilities, I will use this high-level talk to highlight what I regard as a central historiographic problem in the field: the place of culture in our understanding of the development of spaceflight, a problem bound to its theoretical sibling, production. I will approach this claim not through the space history literature but through the broad, postwar intellectual reorientation of the humanities, in which the concepts of production and culture became key sites of theoretical engagement. The underlying question for space history is whether this theorizing and its implications, only loosely grounded in the empirical, provides a means for looking afresh at the field.9

In distilling the postwar theoretical landscape I will necessarily (dangerously) set the “Google map” to a wide view, emphasizing selected features. Soon after Arendt’s *The Human Condition*, notions of production and culture took on new connotations. Production as a form of power, control, and as a technique for replicating and perpetuating particular forms of social life (through capitalist configurations of economic ownership, technology, and labor) came to include also (via the influence of Foucault’s writings) the power attached to scientific disciplines, professions, and the academy, especially when seen historically as coincident with the formation and consolidation of nation-states.0 In concert, culture as an analytic construct enjoyed luxuriant growth, in narrow application (subcultures of every stripe, corporate culture, institutional culture, and the like—think of how unquestionably natural it now seems to speak of “NASA culture”), and in the expansion of its ambit, carried along by the ever-widening reach of commodities and consumer values. Both trends helped to erase the older distinctions of high and low culture and to establish culture as a pervasive conditioner of human affairs. Culture, thus, with protean alacrity, adhered to production in the small (say, within a community, an institution) and in the transnational-spanning large. It served, at once, as energetic contributor to capitalism and as a potential source of resistance. The dominant thread in the mix, at

least as regards theory, focused on big capital, commodities, and consumption.\textsuperscript{11} Culture, in this sense, not only was bound to a particular era of capitalist production, but also participated in an important epistemological shift: In a world of circulating commodities, representations and meanings readily detach from the circumstances of their creation (a basic tenet of poststructuralism, deconstructionism, and postmodernism), become malleable, locally or individually defined. In Western and global capitalism, culture, then, is expressive of production and constitutes a phenomenon that envelops and conditions it. Or, simply, culture becomes self-referential.\textsuperscript{12}

This theoretical neighborhood informed a range of cultural and social fields that emerged in the 1960s and has dominated academic critique since, in part,

\textsuperscript{11} The point here is to emphasize the emergence of culture as a widely used conceptual category. Different definitions of the cultural coexisted under this umbrella. Two of the most influential came from Raymond Williams (culture as a creative intersection between tradition and new experience) and Clifford Geertz (culture as a semiotic system). Particularly relevant here, Williams’s work served as an exemplar in connecting culture and modes of production; see Raymond Williams, \textit{Culture and Society, 1780–1950} (New York: Columbia University Press, 1983) [originally published 1958]. For Geertz, see Clifford Geertz, \textit{The Interpretation of Cultures: Selected Essays} (New York: Basic Books, 1973). Not discussed here is the relation between the “social” and the “cultural” in the academy in this time period; see Victoria Bonnell and Lynn Hunt, eds., \textit{Beyond the Cultural Turn: New Directions in the Study of Society and Culture} (Berkeley, CA: University of California Press, 1999). For a broad review of notions of culture, see Peter Burke, \textit{Varieties of Cultural History} (Ithaca, NY: Cornell University Press, 1997). For the important argument on the historically specific character of the postwar use of culture, see Denning, \textit{Culture in the Age of Three Worlds}; making a similar case is Geoff Eley, \textit{A Cooked Line: From Cultural History to the History of Society} (Ann Arbor, MI: University of Michigan Press, 2005).

\textsuperscript{12} It is important to distinguish two threads of this claim. One is a general epistemological claim on the foundations of knowledge: the view that we have no privileged a priori or empirical means to assess the validity of propositions about the world. The other is historically grounded: that an emergent postwar commercial and communications culture created a new relation between signs and the real and the cultural status and use of such signs. This work built on Marx’s early arguments on the commodity as “fetish.” This view is most thoroughly developed in Jean Baudrillard, \textit{For a Critique of the Political Economy of the Sign} (St. Louis, MO: Telos Press, 1981).
because it offered a first-order cut at defining and investigating basic questions. It pushed to the fore questions of causation: How and why modes of production change and, in turn, are related to and interact with reshaped social or cultural orders. In highlighting causation, it made questions of periodization, of alertness to patterns of change, an explicit, necessary project.

Consider the colloquialism that provided the organizing idea for this conference (and as an assumption only is occasionally engaged by the papers)—that spaceflight “impacts” society and by implication that such effect is historically descriptive and serves as an important basis for conceptualizing research. The first part of this claim is trivially true in a limited way but obscures a more cogent historical question: How do we theorize the relation between spaceflight and the social? Or, more aptly and fundamentally, to build on the interpretive sketch advanced here, how do we theorize spaceflight in and as part of a causally informed history?

In space history, “impact” seems a natural category because of the privileged role ascribed to state-centered action in cold war historical accounts. The invigoration of government-directed power and action postwar (especially in the United States) gives credence to a rough causal formula of “the state acts, society receives.” Or, to venture a touch more complexity, each may affect the other, but each stands as a relatively distinct sphere of activity. Few, if any, historians would subscribe overtly to this cartoonish causal sketch, yet the field has been noticeably slow to articulate more robust frames of analysis. In this conference, authors joined social and cultural with politically centered narratives but leaned away from considering underlying causal issues or broader frames of theoretical interpretation. In terms of engagement

13. This thumbnail is not meant to supplant or diminish other key analytic concepts such as class, gender, or race, or the related pairing of identity and difference. Culture and production may complement or serve as tools for understanding how these other categories may be constituted. Too, the emphasis on culture highlights the way in which, over this time period, anthropology (in particular) and sociology have been the crucial intellectual sites for working through the implications of theoretical claims generated in philosophy, literary criticism, and intellectual history. A focal point, relevant to this essay, for examining this process is the material culture literature, which largely originated in the 1960s. See especially the work of Daniel Miller, founding editor of the journal Material Culture; books include Daniel Miller, Capitalism: An Ethnographic Approach (Oxford: Berg, 1997); Daniel Miller, ed., Material Cultures: Why Some Things Matter (Chicago: University of Chicago Press, 1998); Daniel Miller, ed., Materiality (Durham, NC: Duke University Press, 2005). In this vein, see also Arjun Appadurai, ed., The Social Life of Things: Commodities in Cultural Perspective (Cambridge, U.K.: Cambridge University Press, 1986); Bill Brown, ed., Things (Chicago: University of Chicago Press, 2004); Nicholas Thomas, Entangled Objects: Exchange, Material Culture, and Colonialism in the Pacific (Cambridge, MA: Harvard University Press, 1991); and Fred R. Myers, ed., The Empire of Things: Regimes of Value and Material Culture (Santa Fe, NM: School of American Research Press, 2001). On theory in relation to material culture, see especially Pierre Bourdieu, The Logic of Practice (Stanford, CA: Stanford University Press, 1990), and Jean Baudrillard, Selected Writings (Stanford, CA: Stanford University Press, 2001).
with other historical subfields, this represents a measure of progress but leaves unaddressed the deeper challenges of using available theoretical tools to clarify the field’s explanatory aims—of placing spaceflight \textit{in} history.\textsuperscript{14}

And that brings us back to Arendt, the tradition of Marxian sociological critique of which her work is part, and the analysis presented here.\textsuperscript{15} This analytic frame has deep relevance to post–World War II historiography, including and especially for spaceflight. It cautions us to de-center the importance given to state political action and actors in trying to understand historical change; that is, it suggests that the crucial unit of analysis is not the state in isolation, or even the “contract state” or “military-industrial-university complex” (as widely used constructs attentive to government–market interdependencies).\textsuperscript{16} Rather, it directs our attention to the largest configurations of production—of the state in conjunction with capitalism writ large (to include the academy as it constitutes disciplines and professions).\textsuperscript{17} Arendt’s fleeting attention to Sputnik was to make this theoretical point and to situate the event historically—to ask how the first satellite and the emerging effort of spaceflight fit into a \textit{particular} configuration of production (state and capital) and culture. That question should be as paramount for space history as it was for Arendt.

In the 1960s and after, a torrent of literature concerned with production and culture yielded theoretically infused, historically specific, profound claims regarding the postwar years: that the basis of production \textit{and} the basis of culture had been transformed, reconfiguring each and, to use Arendt’s labeling, the human condition.\textsuperscript{18} Business, markets, and nation-state prerogatives and power changed; postcolonial and new forms of global politics and geographies emerged; and, above all (especially

\textsuperscript{14} For a related example of this type of exercise, reflecting a different historiographic moment, see Eric Hobsbawm, “From Social History to the History of Society,” \textit{Daedalus} 100 (1971): pp. 20–45. For a review of the space history literature that samples a range of current methodologies but is relatively silent on the issue of relating the field to broader theoretical accounts, see Roger D. Launius, “Interpreting the Moon Landings: Project Apollo and the Historians,” \textit{History and Technology} 22 (2006): pp. 225–255.

\textsuperscript{15} I loosely confederate under the banner of Marxian sociology a broad range of authors and perspectives, including those that fall on a spectrum of sympathy or antipathy to Marxian \textit{politics} (consider, say, the work of Frederic Jameson and Daniel Bell). The circumstance that this essay points to is the deep sway of Marxian modes of explanation in the historical and cultural studies fields and the still-powerful utility of a structural analysis in probing issues of causation. Even the poststructuralist and postmodern literatures that see history as composed of texts and representations loosened from any notion of a substantial historical reality don’t quite succeed in diminishing history to mere narrative.

\textsuperscript{16} On the notion of the United States as a contract state, see H. L. Nieburg, \textit{In the Name of Science} (Chicago: Quadrangle Books, 1966).

\textsuperscript{17} For a useful instance of engagement with issues of causation and periodization relevant to this essay, see Ann Douglas, “Periodizing the American Century: Modernism, Postmodernism, and Postcolonialism in the Cold War Context,” \textit{Modernism/Modernity} 5 (1998): pp. 71–98. Douglas is skeptical of the various “isms” of critique but relays fundamentally on the notion of Marxian sociology sketched here.

\textsuperscript{18} The clearest exposition of these claims is David Harvey, \textit{The Condition of Postmodernity: An Enquiry into the Origins of Cultural Change} (Oxford, U.K.: Blackwell Publishers, 1989).
given the topic of this conference), that culture (as embodied in commodities, transnational business practices, and ever more ubiquitous communications and media technologies) was not merely a glossy coat of paint on capitalism’s formidable machine but integral to it and constituted a potent, complementary reality. The insights relating to causation and periodization in this swath of research and theory have remained at the margins of space history, despite the obvious: The changes mapped and claimed are coeval and intimately bound to the development of spaceflight—in its many dimensions as technology, site of knowledge creation, state activity, business undertaking, military venture, global utility, and national and international cultural trope extraordinaire. Can space history be history without more fundamentally assessing and testing itself against this theoretical frame, seemingly, at first pass, deeply relevant to the field’s research challenges (allowing for many the points of disputation on methodology, cause, and consequence contained in this unwieldy set of literatures)? Not just to import methods into the field, but to wrestle with problems of cause and change alongside other humanistic disciplines? The state-centered narratives that seemed passably suitable in the early years of the field now seem increasingly inadequate for reinterpreting the early cold war and, especially, to organize the history of recent decades. The rest of this essay will look briefly at the two nodes of this analysis—production and culture—and their implications for situating spaceflight in this broader landscape of the postwar historical experience.

After World War II, the United States, in a series of steps in collaboration with business and the academy, created, to use Daniel Yergin’s coinage, a national security state. Assessments of its relation to modes of production and shifts in the cultural landscape surfaced in short order. But broad views that an assertive policy of massive government spending on research, development, discipline-centered knowledge, and technology was providing an opportunity to refashion the very basis of capitalism took longer to arise. Emblematic in this regard was the work of the politically liberal economist John Kenneth Galbraith and the conservative

19. On the national security state, see Daniel Yergin, Shattered Peace: The Origins of the Cold War and the National Security State (Boston: Houghton Mifflin, 1977). My analytic focus here is the United States. The goal is not a comprehensive historiographic review and argument; rather, it is only to suggest underlying research problems for the field. It should be noted, though, that the literature on the transformation of capitalism in the 1960s and 1970s is U.S.-centric, given the United States’ dominant economic position.

20. Critiques and targeted assessments were prevalent throughout the late 1940s and 1950s. See, as but one example, C. Wright Mills, The Power Elite (New York: Oxford University Press, 1959).

21. In my reading, most of the early literature envisions the military-industrial-academic complex as an adjunct to the broader economic system of capitalism. The focus tends to be on distortion rather than on a reconstitution of economic structures. The distortion view is the organizing idea of the classic study by RAND economist Charles Hitch. See Charles Johnston Hitch, The Economics of Defense in the Nuclear Age (Cambridge, MA: Harvard University Press, 1960).
sociologist Daniel Bell. By 1960, both had examined capitalism’s condition sans consideration of the cold war elephant in the room. Galbraith’s 1958 *The Affluent Society* explored the cultural changes accompanying widespread consumerism (a theme already much in the air, as indicated by Arendt’s exposition); Bell’s 1960 *The End of Ideology: On the Exhaustion of Political Ideas in the Fifties* claimed that the long-standing tussle between capital and labor had petered out. A triangulation of accommodation among labor, business, and the state, he argued, dampened the conflicting ideological positions of Marxian and capital-oriented politics. In short, both authors saw the defining issues of the 1950s in conceptual terms consistent with the political economy of the early twentieth century. But each, as a consequence of these researches, immediately began a reappraisal of the postwar landscape.

By the late 1960s, Galbraith and Bell made their central research concern the question of whether capitalism and the state, through cold war scientific and technological activism, had revamped existing modes of production. Galbraith’s 1967 *The New Industrial State* and, especially, Bell’s 1973 *The Coming of Post-Industrial Society: A Venture in Social Forecasting* began to make the case that (among other factors) the federal research and development engine had facilitated a fundamental change in business practice, elevating the role of knowledge, and thereby knowledge professions, serving to recast the basic relationship between labor and capital. This reconfiguration had many other elements, including a policy shift that loosened government controls over markets and corporations (nationally and internationally), the burgeoning possibilities of information technologies, and the enhanced role

---

of consumption in economic and cultural life. A range of authors came to see this complex of changes as the seedbed of globalism (conceived as the relative enhancement of the power of markets in relation to states across the transnational landscape) and postmodernism (conceived as a new cultural condition associated with this mode of production). This sparse delineation of this significant shift, played out over two-plus decades, is intended only for a limited point: that spaceflight—in its civil, military, commercial dimensions—developed and participated in fundamental changes in state-market regimes. Thus, if explanation (whether of “impact,” of causes, or patterns of change) is a goal, then such explanation needs to encompass, as a first-order concern, how nation-state-centered accounts relate to the different frames of analysis suggested by globalism and postmodernism. But these points bring us back to the other, crucial question of this review: What is the relation between modes of production and culture in the age of spaceflight?

26. Much of the globalism literature makes the case for the diminishment of nation-state power in face of the market. A cogent analysis of the relation among markets, states, and ideology is Therborn, “After Dialectics.”
This question vexes space history—all the more for lack of explicit theoretical attention. For it is in the very period in which spaceflight develops that culture becomes an historically specific, key concept—as an analytical instrument within the academy and as a descriptor of the broad phenomenological effect of commerce, commodities, and communications on our day-to-day perceptions and constitution of the world. In this latter regard, it embodies deep claims, ontological and psychological: that time, distance, what counts as global or local, and how identities are constituted (ours and those of distant others) all are conceptualized and experienced in new ways. Such propositions became commonplace in the globalism and postmodernism literatures. Philosopher Langdon Winner, as one example, captured this melding of productive regimes, technology, global-local perceptions, and individual identity and their close association with the construct of culture:

The map of the world shows no country called Technopolis, yet in many ways we are already its citizens. If one observes how thoroughly our lives are shaped by interconnected systems of modern technology, how strongly we feel their influence, respect their authority and participate in their workings, one begins to understand that, like it or not, we have become members of a new order in history. To an ever-increasing extent, this order of things transcends national boundaries to create roles and relationships grounded in vast, complex instrumentalities of industrial production, electronic communications, transportation, agribusiness, medicine, and warfare. Observing the structures and processes of these vast systems, one begins to comprehend a distinctively modern form of power, the foundations of technopolitan culture.

27. Of course, the cultural has long been on space history’s radar. In Howard McCurdy’s oft-cited work, the claim is advanced that popular culture helped political elites accept the idea of spaceflight. Missing is theoretical understanding of why that might have been so. See Howard McCurdy, Space and the American Imagination (Washington, DC: Smithsonian Institution Press, 1997). Closer to the mark methodologically is Michael L. Smith, “Selling the Moon: The U.S. Manned Space Program and the Triumph of Commodity Scientism,” in The Culture of Consumption: Critical Essays in American History, 1880–1980, Richard Wightman Fox and T. J. Jackson Lears, eds. (New York: Pantheon, 1982).

In its emphasis on the constitutive role of technology, one easily can read into this description the multiple ways in which the various aspects of spaceflight intersect and participate in this reinvention of the human experience on a global scale. Less evident in Winner’s characterization are the myriad sites of contestation to these changes, the ways in which the local and global get interpreted, defined, and formed by individuals, communities, and nations. Culture, in this argument, is as pervasive as capital and the technological systems with which it is one—not resolutely dominant, but “there” as an element joined, adapted, or countered by many local cultures. It becomes a form of political power and a framework of meanings that may reinforce modernist, nation-state-centered notions of progress, or, or alternatively, in postmodern fashion refer back on itself.

The linkage between culture and capitalism has been strongest in the postmodernist critique, reflecting the seminal influence of Frederic Jameson’s 1984 essay, “Postmodernism, Or, the Cultural Logic of Late Capitalism.” Writing in 1991, Jameson gave the condition described by Winner a different inflection, shifting emphasis from technological systems vast in extent to commodities as key in understanding the status of culture and its relation to changes in the human experience:

Postmodernism is what you have when the modernization process is complete and nature is gone for good. It is a more fully human world than the older one, but one in which “culture” has become a veritable “second nature.” Indeed, what happened to culture may well be of the more important clues for tracking the postmodern: an immense dilation of its sphere (the sphere of commodities), an immense and historically original acculturation of the real “[C]ulture” has become a product in

33. The modernist ideals of progress, especially as adopted by less-developed countries, are a crucial part of geopolitics in this dynamic. They are a resource in defining these nation-states contra to the West. See, for example, Gyan Prakash, *Another Reason: Science and the Imagination of Modern India* (Princeton, NJ: Princeton University Press, 1999).

its own right; the market has become a substitute for itself and fully as much a commodity as any of the items it includes within itself.35

The “dilation” of the congruent spheres of commodities and culture implied not only that more stuff circulated ever more widely through capitalism’s arteries, but also that ever more realms of life—ideas, images, emotions, spirituality, politics—had become commoditized, packaged, and divorced from the circumstances of their creation, infused with the values of the market, including culture itself.

Jameson’s analysis, Marxist and pointedly historical, was not wholly original. In 1961, the more politically and theoretically measured Daniel Boorstin emphasized, too, culture’s historically new and ascendant status, especially as connected to the use of images.

In ... nineteenth-century America the most extreme modernism held that man was made by his environment. In twentieth-century America, without abandoning the belief that we are made by our environment, we also believe our environment be made almost wholly by us. This is the appealing contradiction at the heart of our passion for pseudo events: for made news, synthetic heroes, prefabricated tourist attractions, homogenized forms of art and literature (there are no “originals,” but only the shadows we make of other shadows). We believe we can fill our experience with new-fangled content. Everything we see and hear and do persuades us that this power is ours.36

The primary distinction between the historical-empirical Boorstin and critically inclined Jameson was a profound shift in attitude. Boorstin lamented this undermining of the real; Jameson accepted it as a constitutional feature of capitalism in the latter half of the twentieth century.37

What might we make of these claims binding together epistemology, commodities, and culture conceived as a “second nature”? First is to reemphasize that these are claims about periodization—the making of an era which included spaceflight. As a start, they might encourage us to overlay this analytic on space history’s chronology and look for reorientations that include state-centered politics

37. To Daniel Bell, writing in 1976, Boorstin’s concern loomed large. The abandonment of the real meant abandoning the Protestant ideals of restraint and soberness (borrowing from Max Weber’s classic argument), and thus hollowing out a key pillar of capitalism. Jameson’s account, on this point, seems to have weathered best. See Daniel Bell, The Cultural Contradictions of Capitalism (New York: Basic Books, 1996 [a 20th anniversary edition]).
and happenings in production and culture broadly conceived. A reconceptualization in this vein of the 1960s, for example, might offer interpretations that correlate culture and politics within an integrated frame, rather than as partially overlapping but separate orders of experience. This integration already can be found in several examples of literary criticism that have plumbed space- and business-themed literature. These works employ the same conceptual structure presented here (not surprising) and stand as examples of the explanatory possibilities of this type of analysis. And they raise a deeper point: that in an era of culture, literary tools and modes of analysis may be a necessary complement to history in understanding the human condition. In modernism, the view prevailed that artists stood as critics positioned athwart the culture of their time. In postmodernism and an era of culture as “second nature,” the implied claim is that all historical actors are so suffused with the cultural that no one stands beyond it—we all, in different ways, are users, interpreters, and refashioners in the tide of symbols.

This deep, prosaic sense of culture in the postwar period is the essence of Jameson’s observation. This view marries well with my own research on multinational business and the development of a global satellite telephony system by the Fortune 500 company, Motorola—a subject distant from literary theory but richly indicative of these claims about the status of culture. Culture as preoccupation, conceptual category, and tangible reality suffused Motorola and its development of this satellite project in the later 1980s and 1990s. Such an outlook came to seem essential in running a business with tens of sites around the globe, managing a complex organization, creating new modes of engineering project management, and operating in a media and symbolic environment over which the corporation only had partial control. This culture fixation led the firm to create Motorola University in 1989, with the charge to research and manage the many intersections of culture and corporate practice that now seemed central to the firm’s success. Within the university sat the Center for Technology and Culture, led by an anthropologist who established a range of links to academic anthropology. As the work of these units became integrated into the Motorola business enterprise, they reinforced the view that a necessary relationship existed among culture, the corporation, and an ability to act across the world stage. Motorola University was one notable instance

of a larger trend: over a decade, from the mid 1980s to mid 1990s, more than a thousand corporate universities were created in the United States—all of which were a response, in one fashion or another, to the perceived culture problem and its relation to competition in transnational markets. 40

This example suggests the ways in which culture—and the pursuit of space history—may be intimately bound to configurations of production and politics. 41 More broadly, it suggests the possibilities for space history when we widen the frame of analysis. In emphasizing theory, the argument in this essay is not a call to reductionism, to suggest that richness of historical experience get shoehorned into an empirically contestable structure of critique. Nor is it to minimize the limitations of this theoretical literature. It, by and large, reflects its origination in the Western academy and life experience. Rather, this essay presents a gentle imperative: Be attentive to the possibilities of thought in the humanities that has seen production and culture as a historical problem of the first rank. The notions limned here, as propositions and analytic constructs, provide a basis for reassessing space history’s domain of problems and questions, such as the meaning and status of spaceflight since World War II; its political possibilities; its place in rhetoric and thought in the period; its relation to capital, culture, and commodities; and the combinations of the real, the symbolic, and the imaginary that have gained cultural preference.

In making a profound historical claim that a new configuration of epistemology, production, and culture marks the very period coincident with the development of spaceflight, this body of thought poses a deep challenge to space history. To understand the functioning of symbols and images surfaces as a crucial problem. In what ways, for example, do spaceflight and space fiction—in what balance, with what blurring of genres, of the real and the semiotic—speak to the preoccupations of particular regimes of production and cultural experience? What satisfies and why? What period themes—whether utopia, Earthly escape, the human body, identity, difference—find resonance in the narratives of spaceflight? 42 These are substantial questions that deserve theoretical articulation. Otherwise, our understanding of

41. This perspective is partially realized in Constance Penley, NASA/Trek: Popular Science and Sex in America (London: Verso, 1997).

42. Jameson, the doyen of the capitalist-articulated postmodern, has made science fiction a major theme of his research, reflecting a judgment that the genre is deeply expressive of the period. See Frederic Jameson, Archaeologies of the Future: The Desire Called Utopia and Other Science Fictions (London: Verso, 2005). For an overview of culture-inflected literature in space historiography, see Asif Siddiqi, “American Space History: Legacies, Questions, and Opportunities for Future Research,” in Critical Issues in the History of Spaceflight, Stephen J. Dick and Roger Launius, eds. (Washington, DC: NASA, 2006), pp. 433–480. But, again, the question of how culture might relate to broader problems of explanation in the postwar period are not explicitly addressed.
spaceflight (whether as a state or market undertaking) may remain disconnected from analyses and insights that view production more comprehensively. Without an invigorated conceptual toolbox, the intersection of the cultural and spaceflight may seem primarily as kitsch (Star Trek Enterprise/Space Shuttle Enterprise) or as haphazard and of elusive meaning—rather than as a critical site for investigating the postwar experience.

This analysis offers one path toward a more considered balance between theory and the empirical, toward thinking about spaceflight in history, as a telling angle on our understanding of the late twentieth and early twenty-first centuries.
About the Authors

James T. Andrews is an associate professor of modern Russian and comparative European history in the Department of History at Iowa State University (ISU), where he is co-director of ISU’s Ph.D. program and Center for the Historical Studies of Technology and Science. At ISU, he has also been director of Russian, East European, and Central Asian Studies and director of graduate studies in history. He holds a Ph.D. in modern Russian/Soviet history from the University of Chicago and has taught as a visiting professor at several research institutions, including the University of Texas at Austin. Since the summer of 1995, he has been affiliated as a senior research associate with the Russian Academy of Sciences Institute for the History of the Natural Sciences and Technology in Moscow and St. Petersburg. Professor Andrews’s books and numerous articles have analyzed the intersection of science and technology, society, and public culture in modern Russia and in a comparative Eurasian framework. He is the author of *Science for the Masses: The Bolshevik State, Public Science, and the Popular Imagination, 1917–34* (Texas A&M University Press, 2003) and editor of *Maksim Gor’kii Revisited: Science, Academics and Revolution* (1995). His newest book, to be published in the Texas University Press Centennial of Air-Flight Series, is entitled *Visions of Space Flight: K. E. Tsiolkovskii, Russian Popular Culture, and the Birth of Soviet Cosmonautics, 1857–1957* (forthcoming, 2008). He is also currently completing a monograph (overview synthesis) entitled *Science and the Public Sphere: Technology, Science, and European Public Culture, 1543–Present*.

Linda Billings is a Washington-based research associate with the SETI (Search for ExtraTerrestrial Intelligence) Institute of Mountain View, California. She has been conducting science and risk communication research for NASA’s Planetary Protection Office since September 2002. From September 1999 through August
2002, she was director of communications for SPACEHAB, Inc., a builder of space habitats. Dr. Billings earned her Ph.D. in mass communication from Indiana University's School of Journalism in September 2005. Her expertise is in mass communication, science communication, risk communication, rhetorical analysis, and social studies of science. Her research has focused on the role that journalists play in constructing the cultural authority of scientists and the rhetorical strategies that scientists and journalists employ in communicating about science. She earned her B.A. in social sciences from the State University of New York at Binghamton and her M.A. in international transactions from George Mason University. Dr. Billings has worked for 25 years in Washington, DC as a researcher, journalist, freelance writer, communication specialist, and consultant to the government. As a researcher, she has worked on communication strategy, risk communication, and audience studies for NASA's Planetary Protection program. As a corporate communications director, she was responsible for communications with the media, the public, and the financial community. As a journalist, she covered energy, the environment, labor relations, and aerospace, primarily for the trade press. She was the founding editor of Space Business News (1983–1985) and the first senior editor for space at Air & Space/Smithsonian magazine (1985–1988). She also was a contributing author for First Contact: The Search for Extraterrestrial Intelligence (New American Library, 1990). Dr. Billings was a member of the staff for the National Commission on Space (1985–1986). For the National Science Foundation and NASA, she has worked as a policy analyst, communications specialist, education and outreach planner, and writer and editor. Her freelance articles have been published in outlets such as the Chicago Tribune (“Space Station Is Good for More Than Star-Gazing,” 8 October 1998), the Washington Post Magazine (“Realtime: Pre-Life Sciences,” 11 August 1996) and Space News (“Aim for Exploration, Not Exploitation,” 14–20 October 1996).

Kevin M. Brady is a doctoral candidate in history at Texas Christian University in Fort Worth, Texas, and is studying with Dr. Gregg Cantrell. Brady's classwork and research have focused on Texas history, science and technology, history of NASA, and military history. Currently, Brady is working on a dissertation titled “NASA Launches Houston into Orbit: The Economic, Political, and Social Impact of the Aerospace Program on Southeast Texas, 1961–1969.” In May 2000, Brady earned a B.S. degree in secondary education with a specialization in American history from Baylor University in Waco, Texas. After graduating from Baylor, he remained at the university to pursue graduate work in history. While at Baylor, Brady was the recipient of numerous awards for his academic excellence and dedication to the university. For example, Baylor’s Student Life Division awarded him with the James Huckins Award for Outstanding Graduate Assistant. In August 2002, Brady received an M.A. in history from Baylor University. In the fall of 2002, Brady enrolled at Texas Christian University to pursue doctoral studies in history. From 2003 until 2005, he served as a teaching assistant at Texas Christian University, where he taught U.S. survey courses.
During this time, Brady also worked as an adjunct instructor at the Tarrant County Community College. Brady is the author of several articles and has also contributed to a number of reference works, including *Space Exploration and Humanity: A Historical Encyclopedia*. Currently, Brady serves as a research intern with the Universities Space Research Association (USRA) at the NASA Lyndon B. Johnson Space Center (JSC) in Houston, Texas, where he assists the staff of the JSC History Office.

Andrew Chaikin has authored books and articles about space exploration and astronomy for more than two decades. He is also active as a lecturer at museums, schools, and corporate events, and in radio and television appearances. Chaikin is best known as the author of *A Man on the Moon: The Triumphant Story of the Apollo Space Program*, first published in 1994. This acclaimed work was the main basis for Tom Hanks's HBO miniseries, *From the Earth to the Moon*, which won the Emmy for best miniseries in 1998. Chaikin spent eight years writing and researching *A Man on the Moon*, including hundreds of hours of personal interviews with each of the 23 surviving lunar astronauts. Apollo Moonwalker Gene Cernan said of the book, “I’ve been there.Chaikin took me back.” A three-volume, fully illustrated edition of *A Man on the Moon* was published by Time-Life Books in 1999. Chaikin co-edited *The New Solar System*, a compendium of writings by planetary scientists, now in its fourth edition. He is also the author of *Air and Space: The National Air and Space Museum Story of Flight*, published in 1997 by Bulfinch Press. He collaborated with Moonwalker-turned-artist Alan Bean to write *Apollo: An Eyewitness Account*, published in 1998 by the Greenwich Workshop Press. Chaikin co-authored the text for the highly successful collection of Apollo photography, *Full Moon*, which was published by Knopf in 1999. His book, *SPACE: A History of Space Exploration in Photographs*, was published in 2002 by Carlton Books. In 2004 he authored the chapter on human spaceflight in *The National Geographic Encyclopedia of Space*. From 1999 to 2001 Chaikin served as Executive Editor for Space and Science at SPACE.com, the definitive Web site for all things space. He was also the editor of SPACE.com’s print magazine, *Space Illustrated*. Chaikin is a commentator for National Public Radio’s Morning Edition, and has appeared on Good Morning America, Nightline, and the NPR programs Fresh Air and Talk of the Nation. He has been an advisor to NASA on space policy and public communications. A former editor of *Sky & Telescope* magazine, Chaikin has also been a contributing editor of Popular Science and has written for Newsweek, Air&Space/Smithsonian, World Book Encyclopedia, Scientific American, and other publications. A graduate of Brown University, Chaikin served on the Viking missions to Mars at NASA’s Jet Propulsion Laboratory, and was a researcher at the Smithsonian’s Center for Earth and Planetary Studies before becoming a science journalist in 1980.
Martin J. Collins is a curator in the Smithsonian National Air and Space Museum. He received his Ph.D. from the University of Maryland in history of science and technology. Book publications include *Cold War Laboratory: RAND, the Air Force, and the American State* (2002) and *Showcasing Space*, edited with Douglas Millard, volume 6 of the Artefacts Series: *Studies in the History of Science and Technology* (2005). He is currently working on a history of the Iridium satellite telephone venture.

Erik Conway is the Historian at the Jet Propulsion Laboratory (JPL) of the California Institute of Technology. He is completing a history of atmospheric research at NASA that he started as a contract historian at Langley Research Center in Virginia, and is beginning a history of robotic Mars exploration in the 1980s and 1990s. He has been at JPL since 2004.

Taylor E. Dark, III received his Ph.D. in political science from the University of California, Berkeley and currently teaches in the Department of Political Science at California State University, Los Angeles. He was formerly Associate Dean of the Graduate School of American Studies at Doshisha University in Kyoto, Japan, where he taught for eight years. Professor Dark is the author of *The Unions and the Democrats: An Enduring Alliance* (1999) and has previously published in *The National Interest, Journal of Labor Research, Labor History, Political Science Quarterly, Political Parties, PS: Political Science and Politics*, and *Presidential Studies Quarterly*. He is currently completing a book manuscript on philosophies of space exploration and development in American culture titled “Reclaiming the Future: The Space Program and the Idea of Progress.”

multidisciplinary program in astrobiology. He has served as chairman of the Historical Astronomy Division of the American Astronomical Society and as president of the History of Astronomy Commission of the International Astronomical Union, and he is the immediate past president of the Philosophical Society of Washington. He is a member of the International Academy of Astronautics.

Andrew Fraknoi is the chair of the Astronomy Program at Foothill College near San Francisco. For 14 years, he served as the executive director of the Astronomical Society of the Pacific, the largest and oldest organization devoted to astronomy education. He founded and directed Project ASTRO, a national program that partners volunteer astronomers with fourth- through ninth-grade teachers. A branch of the project has developed family astronomy games and kits and trained educators and amateur astronomers to use them in regional sites from Boston to Hawaii. Fraknoi organized and moderated more than 20 workshops on teaching astronomy in grades 3–12 and four national symposia on teaching introductory astronomy to college nonscience majors. Educated at Harvard and the University of California, Berkeley, Fraknoi has also taught astronomy and physics at San Francisco State University. With Sidney Wolff, he is co-editor of *Astronomy Education Review*, a Web-based refereed journal on education and outreach. Among the books he has written and edited are *Voyages through the Universe* (a college astronomy text), *The Universe at Your Fingertips* (a collection of K–12 activities and resources), and *The Planets and The Universe*, two collections of science and scientifically accurate science fiction. Fraknoi serves on the board of trustees of the SETI Institute and is a fellow of the Committee for the Scientific Investigation of Claims of the Paranormal, specializing in debunking astrology. Awards he has won include the Annenberg Prize of the American Astronomical Society for his contributions to astronomy education. The International Astronomical Union has named Asteroid 4859 Asteroid Fraknoi to recognize his work in astronomy outreach.

Alexander Geppert teaches modern European history at Freie Universität Berlin. He studied history, philosophy, and psychology at Universität Bielefeld, Johns Hopkins University (M.A., 1995) in Baltimore, Georg-August-Universität Göttingen (M.A., 1997), and the University of California, Berkeley. From 1997 to 2004, he was a Ph.D. candidate and research associate at the European University Institute in Florence, where he wrote and defended his dissertation, “London vs. Paris: Imperial Exhibitions, Transitory Spaces and Metropolitan Networks, 1880–1930,” under the supervision of Professors John Brewer, Luisa Passerini, and Bernd Weisbrod. He has held various long-term fellowships at the École des Hautes Études en Sciences Sociales in Paris (1999), the German Historical Institute in London (2000), the Internationales Forschungszentrum Kulturwissenschaften in Vienna (2001–2002), and the Kulturwissenschaftliches Institut in Essen (2002–2005). His work on oral, visual, and urban history (particularly on the history of

Roger Handberg is professor of political science and chair at the University of Central Florida. His published work in space policy and history includes works on NASA, international space commerce, and military space activities. He has published 154 articles and book chapters, 124 professional papers, and 8 books, the most recent being International Space Commerce: Building from Scratch, published in June, 2006 by the University Presses of Florida. Current work involves a study of the Chinese space program and work on nanotechnology policy. Dr. Handberg received his B.A. from Florida State University and Ph.D. from the University of North Carolina.

James R. Hansen is professor of history in the Department of History at Auburn University in Alabama, where he teaches courses on the history of flight, history of science and technology, space history, and the history of technological failure. He has published nine books and three dozen articles on a wide variety of technological topics, ranging from the early days of aviation to the first nuclear fusion reactors, to the Moon landings, to the environmental history of golf course development. His books include First Man: The Life of Neil A. Armstrong (2005); The Bird Is on the Wing: Aerodynamics and the Progress of the Airplane in America (2003); The Wind and Beyond: A Documentary Journey through the History of Aerodynamics in America (Vol. 1, 2002), Spaceflight Revolution (1995), From the Ground Up (1988), and Engineer in Charge (1987). Hansen earned a B.A. degree with high honors from Indiana University (1974) and an M.A. (1976) and Ph.D. (1981) from The Ohio State University. He served as historian for NASA Langley Research in Hampton, Virginia, from 1981 to 1984, and as a professor at the University of Maine in 1984–1985. Professor Hansen has received a number of citations for his scholarship, including the National Space Club’s Robert H. Goddard Award, the Air Force Historical Foundation’s Distinction of Excellence, the American Astronautical Society’s Eugene Emme Prize in Astronautical Literature (twice), the American Institute of Aeronautics and Astronautics’s History Book Award; and AIAA Distinguished Lecturer. He has served on a number of important advisory boards and panels, including the Research Advisory Board of the National Air and Space Museum, the Editorial Advisory Board of the Smithsonian Institution Press, the Advisory Board for the Archives.
of Aerospace Exploration at Virginia Polytechnic Institute and State University, the Museum Advisory Board of the U.S. Space and Rocket Center in Huntsville, Alabama, and the board of directors of the Space Restoration Society. He is a past vice president of the board of directors of the Virginia Air and Space Museum and Hampton Roads History Center in Hampton, Virginia.

Henry R. Hertzfeld is a research professor of Space Policy and International Affairs at the Space Policy Institute, Center for International Science and Technology Policy, Elliott School of International Affairs, George Washington University. He is an expert in the economic, legal, and policy issues of space and advanced technological development and teaches a course in space law as well as one in microeconomics. Dr. Hertzfeld has served as a senior economist and policy analyst at NASA and the National Science Foundation. He has been a consultant to both U.S. and international agencies and organizations, including the Organization for Economic Cooperation and Development, NASA, the Aerospace Corporation, and private companies. He was the co-editor of *Space Economics* (AIAA, 1992) and co-author of *A Study Guide to Managerial Economics* (2005) as well as many articles on the economic and legal issues concerning space and advanced technology. Dr. Hertzfeld has a B.A. from the University of Pennsylvania, an M.A. from Washington University, and a Ph.D. in economics from Temple University. He holds a J.D. degree from the George Washington University and is a member of the bars in Pennsylvania and the District of Columbia.

Stephen B. Johnson is an associate research professor with the Institute for Science and Space Studies at the University of Colorado at Colorado Springs; he is also a health management systems engineer for the Advanced Sensors and System Health Management Branch, NASA Marshall Space Flight Center. He was a faculty member in the University of North Dakota’s Department of Space Studies from 1997 to 2005, teaching military space, space history, and management and economics of space endeavors. He is the author of *The United States Air Force and the Culture of Innovation, 1945–1965* and *The Secret of Apollo: Systems Management in American and
De Witt Douglas Kilgore is associate professor of English and American Studies at Indiana University. He is the author of *Astrofuturism: Science, Race and Visions of Utopia in Space* (2003). In 2001, he received the Science Fiction Research Association’s Pioneer Award for Excellence in Scholarship. Within the field of twentieth-century American literature and culture, he is particularly concerned with exploring the political (utopian) hopes expressed by our society through its projects in science and technology. He is interested in race as both a social and an analytic category. His first book, *Astrofuturism*, is an incisive engagement with the science writing and science fiction produced by the modern spaceflight movement. As a history, it takes seriously the (sometimes progressive) hopes of those scientists and engineers who wrote the Space Age into being as a great cultural project. As a critique, it turns a cold eye on those narratives of disciplined futurism. Kilgore’s current work engages the fiction and science writing that has emerged from SETI (Search for ExtraTerrestrial Intelligence).

John Krige is the Kranzberg Professor in the School of History, Technology and Society at the Georgia Institute of Technology in Atlanta. Krige is a long-time member of the History of Science Society (HSS) and the Society for the History of Technology (SHOT) and has published in the Societies’ journals, *Isis* and *Technology and Culture*. He is also the editor of the journal *History and Technology*, published by Routledge (UK). Krige’s main focus of research is the relationship between foreign policy and science and technology. He played a major role in two international projects that resulted in a three-volume history of CERN (the European Laboratory for Particle Physics) and a two-volume history of ESA (the European Space Agency). Since moving to the United States in the summer of 2000, he has placed increasing emphasis on U.S.–European relationships in science and technology. He is co-editor (with Kai-Henrik Barth of Georgetown University, Washington, DC) of *Global Power Knowledge. Science and Technology in International Affairs*, Osiris 21 (2006), and his most recent book is *American Hegemony and the Postwar Reconstruction*.
About the Authors

of Science in Europe (2006). During academic year 2004–2005, Krije was the Charles A. Lindbergh Professor in Aerospace History at the Smithsonian National Air and Space Museum, Washington, DC. He took this opportunity to initiate research on his next project, which will deal with the role of space technology as an instrument of U.S.–European relations in the 1960s and early 1970s. His preliminary findings were presented as “Technology, Foreign Policy, and International Cooperation in Space,” in Critical Issues in the History of Spaceflight, ed. Steven J. Dick and Roger D. Launius (2006). This project was at the core of Krije’s successful application for a fellowship at the Davis Center, Department of History, Princeton University. Krije was awarded the biennial Dickinson Medal by the (UK) Newcomen Society for the Study of the History of Engineering and Technology in London in May, 2005.

W. Henry “Harry” Lambright is a professor of public administration and political science, and director of the Science and Technology Policy Program at the Maxwell School of Citizenship and Public Affairs at Syracuse University. He teaches courses at the Maxwell School on the intersections of technology, politics, energy, environment, and resources policy. He is a fellow of the American Association for the Advancement of Science. Dr. Lambright has served as a guest scholar at the Brookings Institution, director of the Science and Technology Policy Center of the Syracuse Research Corporation, and director of the Center for Environmental Policy and Administration at the Maxwell School of Syracuse University. He has served as an adjunct professor in the Graduate Program of Environmental Science and Forestry at the State University of New York. He has testified before Congress and consulted for various governmental and private-sector organizations, including the Columbia Accident Investigation Board. He has performed research under support from NASA, the National Science Foundation (NSF), the State Department, the Department of Energy (DOE), the Environmental Protection Agency (EPA), the Department of Defense (DOD), IBM, and other sponsors. A longtime student of large-scale technical projects, and particularly space policy, Dr. Lambright worked for NASA early in his career as a special assistant in its Office of University Affairs. He has been a member of the NASA History Advisory Committee and has written extensively on NASA over many years. He is author of Powering Apollo: James E. Webb of NASA (1995) and editor of Space Policy in the 21st Century (2003). He has written or edited 5 other books and more than 275 articles, reports, and papers. His doctorate is from Columbia University, where he also received his master’s degree. Dr. Lambright received his undergraduate degree from Johns Hopkins University.

Roger D. Launius is a member of the Division of Space History at the Smithsonian Institution’s National Air and Space Museum in Washington, DC. Between 1990 and 2002, he served as Chief Historian of NASA. A graduate of Graceland College in Lamoni, Iowa, he received his Ph.D. from Louisiana State University, Baton Rouge, in 1982. He has written or edited more than 20 books on aerospace history,
including Space: A Journey to Our Future (2004); Space Stations: Base Camps to the Stars (2003), which received the AIAA’s History Manuscript Prize; Flight: A Celebration of 100 Years in Art and Literature (2003); Reconsidering a Century of Flight (2003); To Reach the High Frontier: A History of U.S. Launch Vehicles (2002); Imagining Space: Achievements, Possibilities, Projections, 1950–2050 (2001); Reconsidering Sputnik: Forty Years Since the Soviet Satellite (2000); Innovation and the Development of Flight (1999); Frontiers of Space Exploration (1998; rev. ed., 2004); Spaceflight and the Myth of Presidential Leadership (1997); and NASA: A History of the U.S. Civil Space Program (1994; rev. ed. 2001). He is frequently consulted by the electronic and print media for his views on space issues. His research interests encompass all areas of U.S. and space history and policy history, especially cultural aspects of the subject and the role of executive decision makers and their efforts to define space exploration.

John M. Logsdon is the director of the Space Policy Institute at George Washington University’s Elliott School of International Affairs, where he is also professor of international affairs. He holds a B.S. in physics from Xavier University (1960) and a Ph.D. in political science from New York University (1970). Dr. Logsdon’s research interests focus on the policy and historical aspects of U.S. and international space activities. Dr. Logsdon is the author of The Decision to Go to the Moon: Project Apollo and the National Interest (1970) and is the general editor of the eight-volume NASA History series Exploring the Unknown: Selected Documents in the History of the U.S. Civil Space Program (1995– ). He has written numerous articles and reports on space policy and history. He is frequently consulted by the electronic and print media for his views on space issues. In 2003, Dr. Logsdon served as a member of the Columbia Accident Investigation Board. He is a member of the NASA Advisory Council and of the Commercial Space Transportation Advisory Committee of the Department of Transportation. He is a recipient of the NASA Public Service and Distinguished Public Service Medals, the 2005 John F. Kennedy Award from the American Astronautical Society (AAS), and the 2006 Barry Goldwater Space Educator Award from the American Institute of Aeronautics and Astronautics (AIAA). He is a fellow of the American Institute of Aeronautics and Astronautics and of the American Association for the Advancement of Science (AAAS), and he is a member of the International Academy of Astronautics.

M. G. Lord is a cultural historian and investigative journalist. She is the author of Astro Turf: The Private Life of Rocket Science (2005) and Forever Barbie: The Unauthorized Biography of a Real Doll (1994, 2004). Since 1995 she has been a frequent contributor to The New York Times Book Review and The New York Times Arts & Leisure Section. Her work has appeared in numerous publications, including The Wall Street Journal, The Los Angeles Times Book Review, The New Yorker, ArtForum, and Vogue. For 14 years she was a syndicated political cartoonist based at Newsday. She currently lives in Los Angeles, where she teaches a nonfiction workshop in the Master of Professional Writing Program at the University of Southern California.
Howard E. McCurdy is a professor of public affairs at American University in Washington, DC. Author or co-author of six books on the U.S. space program, he is best known for *Space and the American Imagination* (1997). He authored *Faster, Better, Cheaper* (2001), a critical analysis of cost-cutting initiatives in the U.S. space program, and an earlier study of NASA’s organizational culture, *Inside NASA*, won the 1994 Henry Adams Prize for that year’s best history on the federal government. He is often consulted by the media on public policy issues and has appeared on national news outlets such as *NewsHour with Jim Lehrer*, National Public Radio, and *NBC Nightly News*. Professor McCurdy received his bachelor’s and master’s degrees from the University of Washington and his doctorate from Cornell University.

Kim McQuaid is a professor of history at Lake Erie College in Painesville, Ohio. He received his undergraduate degree in history at Antioch College and his master’s degree and Ph.D. in U.S. history at Northwestern University. He was a Woodrow Wilson Fellow in 1970 and has held several Fulbright overseas teaching positions: first as Mary Bell Washington Visiting Professor of U.S. History at the University College Dublin in 1985–1986, and later as a visiting lecturer in U.S. history at the University of Science in Penang, Malaysia’s second-oldest national university campus, in 1995–1996. McQuaid’s books are *Creating the Welfare State* (co-authored with Edward Berkowitz); *Big Business and Presidential Power* (1982); *The Anxious Years: America in the Vietnam-Watergate Era* (1989); and *Uneasy Partners: Big Business in American Politics, 1945–1990* (1993); and *A Response to Industrialism: Liberal Businessmen and the Evolving Spectrum of Capitalist Reform, 1886–1960* (2003). He is a contributor to academic and nonacademic journals. His most recently published academic piece is “Selling the Space Age: NASA and Earth’s Environment, 1958–1990,” which appeared in *Environment and History*, a journal published in the United Kingdom. He is a member of three space advocacy groups and as many environmental groups. He is also a regular visitor to the high Arctic of Canada and, most recently, Norway; most of these trips have been wilderness travel. He began to try and grow old gracefully on a Russian scientific survey vessel with an ice-hardened hull. He is currently at work on a social history of the Space Age. A native of rural Maine, he has worked as an antiquarian bookseller and a psychiatric social worker in addition to being an academic.

Wendell Mendell is a planetary scientist serving as the manager of the Office for Human Exploration Science of the NASA Johnson Space Center, where he has been employed since 1963. He is married and has four children. Dr. Mendell has a B.S. in physics from the California Institute of Technology, an M.S. in physics from the University of California, Los Angeles (UCLA), and an M.S. in space science and a Ph.D. in space physics and astronomy from Rice University. His scientific research focus is remote sensing of planetary surfaces, particularly specializing in thermal emission radiometry and spectroscopy of the Moon. Since 1982, he has worked at NASA on planning and advocacy of human exploration of the solar system, especially on the establishment of a permanent human base on the Moon.
His interests in this regard lie as much with policy issues as with technical solutions. He is most well known as the editor of the volume *Lunar Bases and Space Activities of the 21st Century*, and he received the 1988 Space Pioneer Award for Science and Engineering from the National Space Society for this work. Currently, Dr. Mendell splits his time between communicating the principles of the human exploration of the solar system to both lay and technical audiences and working on lunar research. He is a member of the College of Teachers of the International Space University (ISU). At the ISU, he has led “Design Projects for an International Lunar Base” (1988); “International Mars Mission” (1991); “International Lunar Farside Observatory and Science Station” (1993); “Vision 20/20” (1995), a sampling of the future as seen by young space professionals; and “Space Tourism: From Dream to Reality” (2000). He belongs to several professional scientific and engineering societies. He is most active in the International Academy of Astronautics, where he has served as secretary of the Cosmic Study on International Human Exploration of Mars and is currently serving on Academic Commission III; and in the AIAA, where he has chaired the Space Science and Astronomy Technical Committee and sits on the International Activities Committee. He served on (and chaired) the Executive Committee of the Aerospace Division of the American Society of Civil Engineers. He has served as editor for nine technical volumes and has published more than 40 articles in professional journals and conference proceedings. He is also the author of numerous abstracts and short papers presented at technical conferences.

**Ron Miller** is the author/illustrator of some 40 books, most of them dealing with space exploration, astronomy, and other sciences. These include the award-winning *Worlds Beyond* series of astronomy books for young adults and *The Art of Chesley Bonestell* (2000), a biography of the grand master of astronomical art. He has also collaborated on five books with noted astronomer William K. Hartmann. These include *The Grand Tour, Cycles of Fire, In the Stream of Stars*, and *The History of Earth* (all published by Workman Publishing Co.). Considered an authority on Jules Verne, Miller has translated and illustrated new, definitive editions of Verne’s *20,000 Leagues Under the Sea* and *Journey to the Center of the Earth*. A book published in July, 1993, *The Dream Machines* (a comprehensive, quarter-million-word, 744-page history of manned spacecraft) was nominated for the prestigious IAF Manuscript Award and won the Booklist Editor’s Choice Award for 1994. He designed a set of 10 commemorative space exploration stamps for the U.S. Postal Service, one of which is on-board the New Horizons spacecraft bound for Pluto. A current project is the reprinting of classic and little-known space travel novels from the past 200 years.

**Valerie Neal** has been a space history curator at the Smithsonian National Air and Space Museum since 1989, where she engages in scholarly research, exhibit development, artifact collection, and public service. She has edited two books on space exploration and curated two major exhibitions on the space race and the challenges of future
About the Authors

Exploration. Most recently, she led the effort to restore the Space Shuttle Enterprise for permanent display and to acquire SpaceShipOne for the national collection. Her recent articles on Shuttle history have appeared in History and Technology and Space Policy. Her current projects are a book and exhibition on the Space Shuttle era. Before joining the Smithsonian, Neal spent a decade as a writer, editor, and manager for some 50 NASA publications on Shuttle and Spacelab missions, the Great Observatories, the space sciences, and NASA history. She also participated in astronaut training activities and worked on the mission management team for four Shuttle missions. Neal earned graduate degrees in American studies from the University of Southern California (M.A.) and the University of Minnesota (Ph.D.). She has taught at the University of Minnesota, the University of Alabama in Huntsville, and Vanderbilt University.

Jennifer Ross-Nazzal currently serves as the historian for the NASA Johnson Space Center (JSC) in Houston, Texas and is a member of the editorial board for Quest: The History of Spaceflight Quarterly. Ross-Nazzal began working for JSC in the summer of 2000 when she received an internship with the Johnson Space Center Oral History Project. In her position as historian, she has conducted more than 86 interviews for the Johnson Space Center Oral History Project and the NASA Headquarters History Office. From 2002 to 2004, she served as the oral history editor for Quest. Ross-Nazzal also participated in the Columbia Recovery Oral History project and later took the lead in a series of interviews to explore NASA’s role in the development of microelectromechanical systems. In addition to her work for the JSC History Office, she works as an adjunct instructor for the University of Maryland University College, where she teaches U.S. and women’s history. Ross-Nazzal received her M.A. in history from New Mexico State University in 1996 and her Ph.D. in history from Washington State University in May, 2004. Her dissertation, which was nominated for the David H. Stratton Award for the department’s best dissertation, the Lerner-Scott Dissertation Prize, and the Phi Alpha Theta/Westerners International Dissertation Prize, focused on the life and times of suffragist Emma Smith DeVoe. Ross-Nazzal is currently revising her dissertation for publication. Two articles spun off from her dissertation have been published by the Pacific Northwest Quarterly and South Dakota History. Among her many honors and awards, she received a practicum grant from the Woodrow Wilson National Fellowship Foundation, and she is a former graduate fellow at the Thomas S. Foley Institute for Public Policy and Public Service. Most recently, she received the HRA New Professional Award from the National Council on Public History.

Philip Scranton is University Board of Governors Professor, History of Industry and Technology, at Rutgers University, where he directs the M.A. history program (Camden) and assisted in developing a Ph.D. field in the History of Technology, Environment and Health (New Brunswick). He served the Georgia Institute of Technology as Kranzberg Professor of the History of Technology and Science from
1997 to 1999. Professor Scranton also directs the Hagley Museum and Library’s research arm, the Center for the History of Business, Technology and Society, with responsibility for a seminar series, twice-yearly conferences, short-term fellowships, and consultation on collections, programs, and planning. During 2003–2004, he held the Lindbergh Chair in Aeronautic and Aerospace History at the Smithsonian’s National Air and Space Museum. His publications include 5 books and 35 scholarly articles; multiple contributions to museum catalogs; and numerous reviews of books, conferences, and exhibits. Since 1985 he has presented research papers at 38 international conferences in Europe, Canada, and Japan. Most recently, Princeton University Press released his *Endless Novelty: Specialty Production and American Industrialization, 1865–1925* (1997, paperback 2000, Japanese translation, 2004). Earlier monographs include *Proprietary Capitalism* (1983) and *Figured Tapestry* (1989), which received the SHEAR and Taft prizes, respectively. At present, Scranton is editor or co-editor of two book series: Studies in Industry and Society (Johns Hopkins University Press) and Hagley Perspectives on Business and Society (formerly Routledge, presently Macmillan, with Roger Horowitz). He has edited or co-edited three volumes in the Hagley Series. In addition, Scranton served the Business History Conference as president (2002–2003) and its journal, *Enterprise and Society* (Oxford University Press), for four years as its initial associate editor for reviews. He is a member of the editorial boards of *Technology and Culture*, *Business History Review*, and *Pennsylvania History*. Born in 1946 in western Pennsylvania, Scranton received undergraduate and graduate degrees in history from the University of Pennsylvania (Ph.D., 1975). He taught at the Philadelphia College of Textiles and Science (1974–1984) before joining the faculty at Rutgers-Camden (1984–1997), moving to Georgia Tech, then returning to Rutgers in fall, 1999. His current research project examines the course of specialty manufacturing in the United States during the Cold War, with a focus on jet propulsion and NASA space capsules.

**Asif A. Siddiqi** is an assistant professor of history at Fordham University in New York. He specializes in the social and cultural history of technology and modern Russian history. His forthcoming book, *The Rockets’ Red Glare: Spaceflight and the Russian Imagination, 1857-1957*, will be published in 2008. He is also working on a project on technology, authenticity, and the evolution of rock’n’roll.

**Rick W. Sturdevant** is the deputy director of history at Headquarters Air Force Space Command, Peterson Air Force Base, in Colorado Springs, Colorado. He holds B.A. (1969) and M.A. (1973) degrees in history from the University of Northern Iowa and a Ph.D. (1982) from the University of California, Santa Barbara. Dr. Sturdevant joined the United States Air Force history program in April, 1984 as the chief historian for Air Force Communication Command’s Airlift Communications Division at Scott Air Force Base, Illinois. In April, 1985 he moved to Peterson Air Force Base, Colorado to become the chief historian for Space Communications
Division. He held that position until the division was inactivated in 1991, at which time he moved to the Air Force Space Command History Office. Dr. Sturdevant has published extensively on the subject of military aerospace history in such periodicals as *Space Times*, *Journal of the British Interplanetary Society*, *Air & Space/Smithsonian*, *Quest: The History of Spaceflight Quarterly*, *Air Power History*, *Air Force Magazine*, *High Frontier: The Journal for Space & Missile Professionals*, and *Journal of the West*. He has authored or co-authored chapters or essays in *Beyond the Ionosphere: Fifty Years of Satellite Communication* (1997); *Organizing for the Use of Space: Historical Perspectives on a Persistent Issue* (1995); *Golden Legacy, Boundless Future: Essays on the United States Air Force and the Rise of Aerospace Power* (2000); *Air Warfare: An International Encyclopedia* (2002); *To Reach the High Frontier: A History of U.S. Launch Vehicles* (2002); *The Limitless Sky: Air Force Science and Technology Contributions to the Nation* (2004); and *Encyclopedia of 20th-Century Technology* (2005). A frequent lecturer on space history topics, he has taught Elderhostel and Pillar courses under the sponsorship of Pikes Peak Community College in Colorado Springs and was a guest speaker at the 2005 High Plains Chautauqua in Greeley, Colorado. Dr. Sturdevant is an active member of the American Institute of Aeronautics and Astronautics (AIAA), British Interplanetary Society (BIS), Air Force Space Operations Association (AFSOA), Society for the History of Technology (SHOT), and American Astronautical Society (AAS). Serving on the AAS History Committee, he has participated for nearly a decade in selecting the annual recipient of the Eugene M. Emme Astronautical Literature Award. He is a recipient of the Air Force Exemplary Civilian Service Award and the AAS President’s Recognition Award.

James A. Vedda joined The Aerospace Corporation in March 2004 to perform research and analysis on national security, civil, and commercial space issues. Previously, he spent six and a half years at ANSER Inc. in Arlington, Virginia, assigned full-time to the Office of the Secretary of Defense. This included two years with the assistant secretary for Homeland Defense and four and a half years in the Space Policy Directorate. While at ANSER, Dr. Vedda received the company’s highest employee award, the Alan S. Boyd Award for Professional Development, in 2002; an annual Trustee’s Award and a quarterly Team Excellence Award in 2003; and several awards for publications throughout his tenure. Jim received his Ph.D. in political science from the University of Florida. His dissertation analyzed the evolution of post-Apollo space policy making in the executive and legislative branches. He also has an M.A. in science, technology, and public policy from George Washington University in Washington, DC and a B.S in business administration from John Carroll University in Cleveland, Ohio. He has been a member of the American Astronautical Society since 1997, serving as its vice president for public policy from July 2002 to November 2004, and as a member of its board of directors since then. From 1987 to 1993, Jim was a professor in the Department of Space Studies at the University of North Dakota, where he taught courses on civil, commercial, and
military space policy to undergraduate and graduate students. He was one of the founding members of the faculty, helping to create the curriculum for the M.S. in Space Studies degree. He was associate director of North Dakota’s participation in the NASA Space Grant program, served for a period as department chairman, and pioneered the department’s use of multimedia teaching techniques. Jim’s writing has appeared in publications such as *Space Policy*, *Space News*, *Space Times*, *Ad Astra*, *Space Energy and Transportation*, and *Space Business News*. He has presented conference papers and commentary for the International Astronautical Federation, the Midwest Political Science Association, the Public Members Association of the Foreign Service, and CNN.

**Peter J. Westwick** is visiting researcher in history, University of California, Santa Barbara. He was previously an Olin Fellow in international security studies at Yale University and, from 2000 to 2004, senior research fellow in humanities at the California Institute of Technology. He is the author of *The National Labs: Science in an American System, 1947–1974* (2003), which won the 2004 Book Prize of the Forum for the History of Science in America (for best first book), and *Into the Black: JPL and the American Space Program, 1976–2004* (2006). He is currently working on a history of the Strategic Defense Initiative. He received his B.A. in physics and Ph.D. in history from the University of California, Berkeley. He is a moderator of the working group on science and technology at the Institute on California and the West, University of Southern California (USC)/Huntington Library, where he is helping to start an initiative to document the history of the aerospace industry in southern California.

**David J. Whalen** is vice president, satellite systems consulting at IOT Systems LLC. He has been an engineer and engineering manager in the communications satellite industry for more than 30 years. He has also worked on weather satellites (INSAT, GOES-NEXT), Earth observing satellites (Landsat), and science satellites (GRO, Hubble). He is an associate fellow of the American Institute of Aeronautics and Astronautics (AIAA). He has been a member of the AIAA History Technical Committee and is currently a member of the AIAA Communications Systems Technical Committee. Over the last 20 years he has written about space history and space policy in addition to his engineering work. He holds a B.A. in astronomy from Boston University, an M.S. in astronomy from the University of Massachusetts, an M.B.A. from the College of William and Mary, and a Ph.D. in science, technology, and public policy from George Washington University. He has taught university and industrial courses in orbit determination and maneuver planning, satellite communications, space policy, and the history of technology. His book, *Origins of Satellite Communications 1945-1965*, was published by the Smithsonian Institution Press in 2002. He is currently at work on a book about COMSAT Corporation. He
About the Authors

has made many presentations at AIAA, PTC, CASBAA, AHA, SHFG, and NASA conferences. He has published articles and book reviews on space history, space policy, and space technology in a variety of publications, including IEEE Technology and Society and Technology and Culture.

Ray A. Williamson is research professor of space policy and international affairs in the Space Policy Institute, focusing on the applications of geospatial information for the management of natural and cultural resources. He is principal investigator for a NASA/NOAA-funded study of the socioeconomic benefits of earth science. He was also co-investigator of Bridging the Gap: European C4ISR Capabilities and Transatlantic Interoperability (2004), and principal investigator of a two-year study of dual-purpose space technologies (satellite communications; remote sensing; and position, navigation, and timing) for a private foundation. He serves on the National Academy of Sciences Committee on Space-based Global Precipitation Measurements and the Independent Committee to Assess the National Space Weather Program. Dr. Williamson is also a member of the NOAA Advisory Committee on Commercial Remote Sensing (ACRES). From 1979 to 1995, he was a senior associate and project director in the Office of Technology Assessment (OTA) of the U.S. Congress. While at OTA, Dr. Williamson was project director for space policy reports that focused on satellite remote sensing. Dr. Williamson is an external faculty member of the International Space University (ISU), Illkirch, France, teaching general space policy and remote sensing for the ISU Masters of Space Studies and summer session programs. He has lectured on remote sensing policies and markets and the applications of geospatial technologies in regional, national, and international forums. Dr. Williamson received his B.A. in physics from the Johns Hopkins University and his Ph.D. in astronomy from the University of Maryland, and spent two years on the faculty of the University of Hawaii studying diffuse emission nebulae. He taught philosophy, literature, mathematics, physics, and astronomy at St. John’s College, Annapolis for 10 years, the last 5 of which he also served as assistant dean of the college. Dr. Williamson is editor of Imaging Notes and a contributing editor to the journal Space Policy. From 1998–2001 he was a member of the Aeronautics and Space Engineering Board of the National Academy of Engineering. He is also a member of the International Academy of Astronautics. His published books include Bridging the Gap: European C4ISR Capabilities and Transatlantic Interoperability, ed. with Gordon Adams, Guy Ben-Ari, and John M. Logsdon (2004) and Commercial Observation Satellites: At the Leading Edge of Global Transparency, ed. with John C. Baker and Kevin O’Connell (2001).
